

### FEATURES

- 1.8 V analog supply operation
- 1.8 V CMOS or LVDS outputs
- SNR = 71.2 dBFS @ 70 MHz
- SFDR = 93 dBc @ 70 MHz
- Low power: 74 mW/channel ADC core @ 125 MSPS
- Differential analog input with 650 MHz bandwidth
- IF sampling frequencies to 200 MHz
- On-chip voltage reference and sample-and-hold circuit
- 2 V p-p differential analog input
- DNL =  $\pm 0.25$  LSB
- Serial port control options
  - Offset binary, Gray code, or twos complement data format
  - Optional clock duty cycle stabilizer
  - Integer 1-to-8 input clock divider
  - Data output multiplex option
  - Built-in selectable digital test pattern generation
  - Energy-saving power-down modes
  - Data clock out with programmable clock and data alignment

### APPLICATIONS

- Communications
- Diversity radio systems
- Multimode digital receivers
  - GSM, EDGE, W-CDMA, LTE,
  - CDMA2000, WiMAX, TD-SCDMA
- I/Q demodulation systems
- Smart antenna systems
- Broadband data applications
- Battery-powered instruments
- Hand-held scope meters
- Portable medical imaging
- Ultrasound
- Radar/LIDAR

### PRODUCT HIGHLIGHTS

1. The AD9628<sup>1</sup> operates from a single 1.8 V analog power supply and features a separate digital output driver supply to accommodate 1.8 V CMOS or LVDS logic families.
2. The patented sample-and-hold circuit maintains excellent performance for input frequencies up to 200 MHz and is designed for low cost, low power, and ease of use.
3. A standard serial port interface supports various product features and functions, such as data output formatting, internal clock divider, power-down, DCO/data timing and offset adjustments.
4. The AD9628 is packaged in a 64-lead RoHS-compliant LFCSP that is pin compatible with the AD9650/AD9269/AD9268 16-bit ADC, the AD9258/AD9251/AD9648 14-bit ADCs, the AD9231 12-bit ADC, and the AD9608/AD9204 10-bit ADCs, enabling a simple migration path between 10-bit and 16-bit converters sampling from 20 MSPS to 125 MSPS.

## REVISION HISTORY

7/11—Revision 0: Initial Version

## GENERAL DESCRIPTION

The [AD9628](#) is a monolithic, dual-channel, 1.8 V supply, 12-bit, 125 MSPS/105 MSPS analog-to-digital converter (ADC). It features a high performance sample-and-hold circuit and on-chip voltage reference.

The product uses multistage differential pipeline architecture with output error correction logic to provide 12-bit accuracy at 125 MSPS data rates and to guarantee no missing codes over the full operating temperature range.

The ADC contains several features designed to maximize flexibility and minimize system cost, such as programmable clock and data alignment and programmable digital test pattern generation. The available digital test patterns include built-in deterministic and pseudorandom patterns, along with custom user-defined test patterns entered via the serial port interface (SPI).

A differential clock input controls all internal conversion cycles. An optional duty cycle stabilizer (DCS) compensates for wide variations in the clock duty cycle while maintaining excellent overall ADC performance.

The digital output data is presented in offset binary, Gray code, or twos complement format. A data output clock (DCO) is provided for each ADC channel to ensure proper latch timing with receiving logic. 1.8 V CMOS or LVDS output logic levels are supported. Output data can also be multiplexed onto a single output bus.

The [AD9628](#) is available in a 64-lead RoHS-compliant LFCSP and is specified over the industrial temperature range ( $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ ). This product is protected by a U.S. patent.

## SPECIFICATIONS

### DC SPECIFICATIONS

AVDD = 1.8 V, DRVDD = 1.8 V, maximum sample rate, VIN = -1.0 dBFS differential input, 1.0 V internal reference, DCS enabled, unless otherwise noted.

Table 1.

Parameter	Temp	AD9628-105			AD9628-125			Unit

## ABSOLUTE MAXIMUM RATINGS

Table 6.

Parameter	Rating
Electrical <sup>1</sup>	
AVDD to AGND	−0.3 V to +2.0 V
DRVDD to AGND	−0.3 V to +2.0 V
VIN+A/VIN+B, VIN−A/VIN−B to AGND	−0.3 V to AVDD + 0.2 V
CLK+, CLK− to AGND	−0.3 V to AVDD + 0.2 V
SYNC to AGND	−0.3 V to AVDD + 0.2 V
VCM to AGND	−0.3 V to AVDD + 0.2 V
RBIAS to AGND	−0.3 V to AVDD + 0.2 V
CSB to AGND	−0.3 V to DRVDD + 0.2 V
SCLK/DFS to AGND	−0.3 V to DRVDD + 0.2 V
SDIO/DCS to AGND	−0.3 V to DRVDD + 0.2 V
OEB	−0.3 V to DRVDD + 0.2 V
PDWEN	−0.3 V to DRVDD + 0.2 V
D0A/D0B through D11A/D11B to AGND	−0.3 V to DRVDD + 0.2 V
DCOA/DCOB to AGND	−0.3 V to DRVDD + 0.2 V
Environmental	
Operating Temperature Range (Ambient)	−40°C to +85°C
Maximum Junction Temperature Under Bias	150°C
Storage Temperature Range (Ambient)	−65°C to +150°C

<sup>1</sup> The inputs and outputs are rated to the supply voltage (AVDD or DRVDD) + 0.2 V but should not exceed 2.1 V.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THERMAL CHARACTERISTICS

The exposed paddle must be soldered to the ground plane for the LFCSP package. Soldering the exposed paddle to the PCB increases the reliability of the solder joints and maximizes the thermal capability of the package.

Table 7. Thermal Resistance

Package Type	Airflow Velocity (m/sec)	$\theta_{JA}$ <sup>1,2</sup>	$\theta_{JC}$ <sup>1,3</sup>	$\theta_{JB}$ <sup>1,4</sup>	$\Psi_{JT}$ <sup>1,2</sup>	Unit
64-Lead LFCSP 9 mm × 9 mm (CP-64-4)	0	22.3	1.4	N/A	0.1	°C/W
	1.0	19.5	N/A	11.8	0.2	°C/W
	2.5	17.5	N/A	N/A	0.2	°C/W

<sup>1</sup> Per JEDEC 51-7, plus JEDEC 25-5 2S2P test board.

<sup>2</sup> Per JEDEC JESD51-2 (still air) or JEDEC JESD51-6 (moving air).

<sup>3</sup> Per MIL-Std 883, Method 1012.1.

<sup>4</sup> Per JEDEC JESD51-8 (still air).

Typical  $\theta_{JA}$  is specified for a 4-layer PCB with a solid ground plane. As shown Table 7, airflow improves heat dissipation, which reduces  $\theta_{JA}$ . In addition, metal in direct contact with the package leads from metal traces, through holes, ground, and power planes reduces  $\theta_{JA}$ .

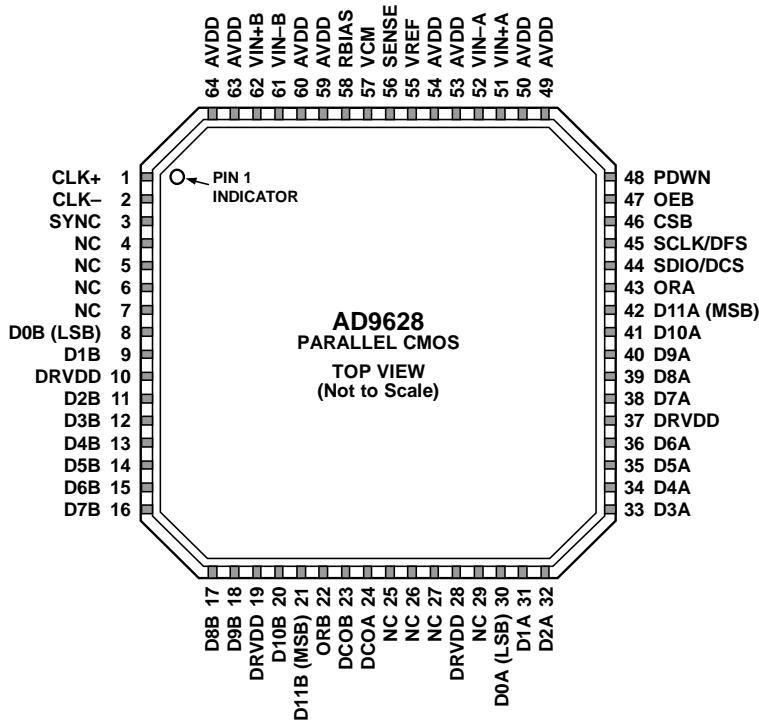

## ESD CAUTION

### ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

# PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

- NOTES**
1. NC = NO CONNECT. DO NOT CONNECT TO THIS PIN.
  2. THE EXPOSED THERMAL PAD ON THE BOTTOM OF THE PACKAGE PROVIDES THE ANALOG GROUND FOR THE PART. THIS EXPOSED PAD MUST BE CONNECTED TO GROUND FOR PROPER OPERATION.

## THEORY OF OPERATION

The AD9628 dual ADC design can be used for diversity reception of signals, where the ADCs are operating identically on the same carrier but from two separate antennae. The ADCs can also be operated with independent analog inputs. The user can sample any  $f_s/2$  frequency segment from dc to 200 MHz, using appropriate low-pass or band-pass filtering at the ADC inputs with little loss in ADC performance. Operation to 300 MHz analog input is permitted but occurs at the expense of increased ADC noise and distortion.

In nondiversity applications, the AD9628 can be used as a base-band or direct downconversion receiver, where one ADC is used for I input data and the other is used for Q input data.

Synchronization capability is provided to allow synchronized timing between multiple channels or multiple devices.

Programming and control of the AD9628 is accomplished using a 3-bit, SPI-compatible serial interface.

### ADC ARCHITECTURE

The AD9628 architecture consists of a multistage, pipelined ADC. Each stage provides sufficient overlap to correct for flash errors in the preceding stage. The quantized outputs from each stage are combined into a final 12-bit result in the digital correction logic. The pipelined architecture permits the first stage to operate with a new input sample while the remaining stages operate with preceding samples. Sampling occurs on the rising edge of the clock.

Each stage of the pipeline, excluding the last, consists of a low resolution flash ADC connected to a switched-capacitor DAC and an interstage residue amplifier (for example, a multiplying digital-to-analog converter (MDAC)). The residue amplifier magnifies the difference between the reconstructed DAC output and the flash input for the next stage in the pipeline. One bit of redundancy is used in each stage to facilitate digital correction of flash errors. The last stage simply consists of a flash ADC.

The output staging block aligns the data, corrects errors, and passes the data to the CMOS/LVDS output buffers. The output buffers are powered from a separate (DRVDD) supply, allowing digital output noise to be separated from the analog core. During power-down, the output buffers go into a high impedance state.

### ANALOG INPUT CONSIDERATIONS

The analog input to the AD9628 is a differential switched-capacitor circuit designed for processing differential input signals. This circuit can support a wide common-mode range while maintaining excellent performance. By using an input common-mode voltage of midsupply, users can minimize signal-dependent errors and achieve optimum performance.

Figure 42. Switched-Capacitor Input Circuit

The clock signal alternately switches the input circuit between sample-and-hold mode (see Figure 42). When the input circuit is switched to sample mode, the signal source must be capable of charging the sample capacitors and settling within one-half of a clock cycle. A small resistor in series with each input can help reduce the peak transient current injected from the output stage of the driving source. In addition, low Q inductors or ferrite beads can be placed on each leg of the input to reduce high differential capacitance at the analog inputs and, therefore, achieve the maximum bandwidth of the ADC. Such use of low Q inductors or ferrite beads is required when driving the converter front end at high IF frequencies. Either a shunt capacitor or two single-ended capacitors can be placed on the inputs to provide a matching passive network. This ultimately creates a low-pass filter at the input to limit unwanted broadband noise. See the AN-742 Application Note, the AN-827 Application Note, and the *Analog Dialogue* article “Transformer-Coupled Front-End for Wideband A/D Converters” (Volume 39, April 2005) for more information. In general, the precise values depend on the application.

# AD9628

## Input Common Mode

The analog inputs of the [AD9628](#) are not internally dc-biased. Therefore, in ac-coupled applications, the user must provide a dc bias externally. Setting the device so that  $V_{CM} = AVDD/2$  is recommended for optimum performance, but the device can function over a wider range with reasonable performance, as shown in Figure 43.

An on-board, common-mode voltage reference is included in the design and is available from the VCM pin. The VCM pin must be decoupled to ground by a 0.1  $\mu F$  capacitor, as described in the Applications Information section.

Figure 43. SNR/SFDR vs. Input Common-Mode Voltage,  $f_{IN} = 70$  MHz,  $f_s = 125$  MSPS

## Differential Input Configurations

Optimum performance is achieved while driving the AD9628 in a differential input configuration. For baseband applications, the [AD8138](#), [ADA4937-2](#), and [ADA4938-2](#) differential drivers provide excellent performance and a flexible interface to the ADC.

The output common-mode voltage of the ADA4938-2 is easily set with the VCM pin of the [AD9628](#) (see Figure 44), and the

driver can be configured in a Sallen-Key filter topology to provide band limiting of the input signal.

Figure 44. Differential Input Configuration Using the ADA4938-2

For baseband applications below  $\sim 10$  MHz where SNR is a key parameter, differential transformer-coupling is the recommended input configuration. An example is shown in Figure 45. To bias the analog input, the VCM voltage can be connected to the center tap of the secondary winding of the transformer.

Figure 45. Differential Transformer-Coupled Configuration

The signal characteristics must be considered when selecting a transformer. Most RF transformers saturate at frequencies below a few megahertz (MHz). Excessive signal power can also cause core saturation, which leads to distortion.

At input frequencies in the second Nyquist zone and above, the noise performance of most amplifiers is not adequate to achieve the true SNR performance of the AD9628. For applications above  $\sim 10$  MHz where SNR is a key parameter, differential double balun coupling is the recommended input configuration (see Figure 46).

An alternative to using a transformer-coupled input at frequencies in the second Nyquist zone is to use the [AD8352](#) differential driver. An example is shown in Figure 47. See the AD8352 data sheet for more information.

Figure 46. Differential Double Balun Input Configuration

Figure 47. Differential Input Configuration Using the AD8352

In any configuration, the value of Shunt Capacitor C is dependent on the input frequency and source impedance and may need to be reduced or removed. Table 11 displays the suggested values to set the RC network. However, these values are dependent on the input signal and should be used only as a starting guide.

Table 11. Example RC Network

Frequency Range (MHz)	R Series (Ω Each)	C Differential (pF)
0 to 70	33	22
70 to 200	125	Open

**Single-Ended Input Configuration**

A single-ended input can provide adequate performance in cost-sensitive applications. In this configuration, SFDR and distortion performance degrade due to the large input common-mode swing. If the source impedances on each input are matched, there should be little effect on SNR performance. Figure 48 shows a typical single-ended input configuration.

Figure 48. Single-Ended Input Configuration

**VOLTAGE REFERENCE**

A stable and accurate 1.0 V voltage reference is built into the AD9628. The VREF can be configured using either the internal 1.0 V reference or an externally applied 1.0 V reference voltage. The various reference modes are summarized in the sections that follow. The Reference Decoupling section describes the best practices PCB layout of the reference.

**Internal Reference Connection**

A comparator within the AD9628 detects the potential at the SENSE pin and configures the reference into two possible modes, which are summarized in Table 12. If SENSE is grounded, the reference amplifier switch is connected to the internal resistor divider (see Figure 49), setting VREF to 1.0 V.

Figure 49. Internal Reference Configuration

If the internal reference of the AD9628 is used to drive multiple converters to improve gain matching, the loading of the reference by the other converters must be considered. Figure 50 shows how the internal reference voltage is affected by loading.

Figure 50. VREF Accuracy vs. Load Current

Table 12. Reference Configuration Summary

Selected Mode	SENSE Voltage (V)	Resulting VREF (V)	Resulting Differential Span (V p-p)
Fixed Internal Reference	AGND to 0.2	1.0 internal	2.0
Fixed External Reference	AVDD	1.0 applied to external VREF pin	2.0

## External Reference Operation

The use of an external reference may be necessary to enhance the gain accuracy of the ADC or improve thermal drift characteristics. Figure 51 shows the typical drift characteristics of the internal reference in 1.0 V mode.

Figure 51. Typical  $V_{REF}$  Drift

When the SENSE pin is tied to AVDD, the internal reference is disabled, allowing the use of an external reference. An internal reference buffer loads the external reference with an equivalent 7.5 k $\Omega$  load (see Figure 41). The internal buffer generates the positive and negative full-scale references for the ADC core. Therefore, the external reference must be limited to a maximum of 1.0 V.

## CLOCK INPUT CONSIDERATIONS

For optimum performance, clock the AD9628 sample clock inputs, CLK+ and CLK-, with a differential signal. The signal is typically ac-coupled into the CLK+ and CLK- pins via a transformer or capacitors. These pins are biased internally (see Figure 52) and require no external bias.

Figure 52. Equivalent Clock Input Circuit

## Clock Input Options

The AD9628 has a very flexible clock input structure. The clock input can be a CMOS, LVDS, LVPECL, or sine wave signal. Regardless of the type of signal being used, clock source jitter is of the most concern, as described in the Jitter Considerations section.

Figure 53 and Figure 54 show two preferred methods for clocking the AD9628 (at clock rates up to 1 GHz prior to internal CLK divider). A low jitter clock source is converted from a single-ended signal to a differential signal using either an RF transformer or an RF balun.

The RF balun configuration is recommended for clock frequencies between 125 MHz and 1 GHz, and the RF transformer is recommended for clock frequencies from 10 MHz to 200 MHz. The back-to-back Schottky diodes across the transformer/balun secondary limit clock excursions into the AD9628 to approximately 0.8 V p-p differential.

This limit helps prevent the large voltage swings of the clock from feeding through to other portions of the AD9628 while preserving the fast rise and fall times of the signal that are critical to a low jitter performance.

Figure 53. Transformer-Coupled Differential Clock (Up to 200 MHz)

Figure 54. Balun-Coupled Differential Clock (Up to 1 GHz)

If a low jitter clock source is not available, another option is to ac couple a differential PECL signal to the sample clock input pins, as shown in Figure 55. The AD9510/AD9511/AD9512/AD9513/AD9514/AD9515/AD9516/AD9517 clock drivers offer excellent jitter performance.

Figure 55. Differential PECL Sample Clock (Up to 1 GHz)

A third option is to ac couple a differential LVDS signal to the sample clock input pins, as shown in Figure 56. The AD9510/AD9511/AD9512/AD9513/AD9514/AD9515/AD9516/AD9517 clock drivers offer excellent jitter performance.

Figure 56. Differential LVDS Sample Clock (Up to 1 GHz)

In some applications, it may be acceptable to drive the sample clock inputs with a single-ended 1.8 V CMOS signal. In such applications, drive the CLK+ pin directly from a CMOS gate, and bypass the CLK- pin to ground with a 0.1 μF capacitor (see Figure 57).

Figure 57. Single-Ended 1.8 V CMOS Input Clock (Up to 200 MHz)

**Input Clock Divider**

The AD9628 contains an input clock divider with the ability to divide the input clock by integer values between 1 and 8.

The AD9628 clock divider can be synchronized using the external SYNC input. Bit 1 and Bit 2 of Register 0x3A allow the clock divider to be resynchronized on every SYNC signal or only on the first SYNC signal after the register is written. A valid SYNC causes the clock divider to reset to its initial state. This synchronization feature allows multiple parts to have their clock dividers aligned to guarantee simultaneous input sampling.

**Clock Duty Cycle**

Typical high speed ADCs use both clock edges to generate a variety of internal timing signals and, as a result, may be sensitive to clock duty cycle. Commonly, a ±5% tolerance is required on the clock duty cycle to maintain dynamic performance characteristics.

The AD9628 contains a duty cycle stabilizer (DCS) that retimes the nonsampling (falling) edge, providing an internal clock signal with a nominal 50% duty cycle. This allows the user to provide a wide range of clock input duty cycles without affecting the performance of the AD9628. Noise and distortion performance are nearly flat for a wide range of duty cycles with the DCS on, as shown in Figure 58.

Jitter in the rising edge of the input is still of concern and is not easily reduced by the internal stabilization circuit. The duty cycle control loop does not function for clock rates less than 20 MHz, nominally. The loop has a time constant associated with it that must be considered in applications in which the clock rate can change dynamically. A wait time of 1.5 μs to 5 μs is required after a dynamic clock frequency increase or decrease before the DCS loop is relocked to the input signal.

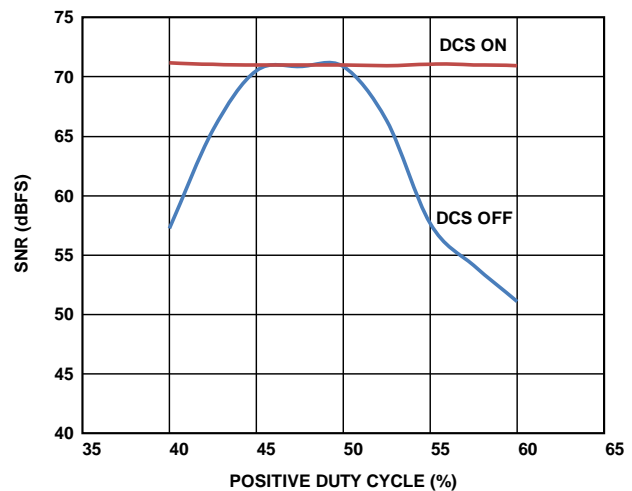

Figure 58. SNR vs. DCS On/Off

## Jitter Considerations

High speed, high resolution ADCs are sensitive to the quality of the clock input. The degradation in SNR from the low frequency SNR ( $SNR_{LF}$ ) at a given input frequency ( $f_{INPUT}$ ) due to jitter ( $t_{JMS}$ ) can be calculated by

$$SNR_{HF} = -10 \log[(2\pi \times f_{INPUT} \times t_{JMS})^2 + 10^{(-SNR_{LF}/10)}]$$

In the previous equation, the rms aperture jitter represents the clock input jitter specification. IF undersampling applications are particularly sensitive to jitter, as illustrated in Figure 59.

Figure 59. SNR vs. Input Frequency and Jitter

The clock input should be treated as an analog signal in cases where aperture jitter may affect the dynamic range of the AD9628. To avoid modulating the clock signal with digital noise, keep power supplies for clock drivers separate from the ADC output driver supplies. Low jitter, crystal-controlled oscillators make the best clock sources. If the clock is generated from another type of source (by gating, dividing, or another method), it should be retimed by the original clock at the last step.

See the AN-501 Application Note and the AN-756 Application Note available on [www.analog.com](http://www.analog.com) for more information.

## CHANNEL/CHIP SYNCHRONIZATION

The AD9628 has a SYNC input that offers the user flexible synchronization options for synchronizing sample clocks across multiple ADCs. The input clock divider can be enabled to synchronize on a single occurrence of the SYNC signal or on every occurrence. The SYNC input is internally synchronized to the sample clock; however, to ensure that there is no timing uncertainty between multiple parts, the SYNC input signal should be externally synchronized to the input clock signal, meeting the setup and hold times shown in Table 5. Drive the SYNC input using a single-ended CMOS-type signal.

## POWER DISSIPATION AND STANDBY MODE

As shown in Figure 60, the analog core power dissipated by the AD9628 is proportional to its sample rate. The digital power dissipation of the CMOS outputs are determined

primarily by the strength of the digital drivers and the load on each output bit.

The maximum DRVDD current ( $I_{DRVDD}$ ) can be calculated as

$$I_{DRVDD} = V_{DRVDD} \times C_{LOAD} \times f_{CLK} \times N$$

where  $N$  is the number of output bits (26, in the case of the AD9628).

This maximum current occurs when every output bit switches on every clock cycle, that is, a full-scale square wave at the Nyquist frequency of  $f_{CLK}/2$ . In practice, the DRVDD current is established by the average number of output bits switching, which is determined by the sample rate and the characteristics of the analog input signal.

Reducing the capacitive load presented to the output drivers can minimize digital power consumption. The data in Figure 60 was taken in CMOS mode using the same operating conditions as those used for the power supplies and power consumption specifications in Table 1 with a 5 pF load on each output driver.

Figure 60. AD9628-125 Power and Current vs. Clock Rate (1.8 V CMOS Output Mode)

Figure 61. AD9648-105 Power and Current vs. Clock Rate (1.8 V CMOS Output Mode)

The AD9628 is placed in power-down mode either by the SPI port or by asserting the PDWN pin high. In this state, the ADC typically dissipates less than 2 mW. During power-down, the output drivers are placed in a high impedance state. Asserting the PDWN pin low returns the AD9628 to its normal operating mode. Note that PDWN is referenced to the digital output driver supply (DRVDD) and should not exceed that supply voltage.

Low power dissipation in power-down mode is achieved by shutting down the reference, reference buffer, biasing networks, and clock. Internal capacitors are discharged when entering power-down mode and then must be recharged when returning to normal operation. As a result, wake-up time is related to the time spent in power-down mode, and shorter power-down cycles result in proportionally shorter wake-up times.

When using the SPI, the user can place the ADC in power-down mode or standby mode. Standby mode allows the user to keep the internal reference circuitry powered when faster wake-up times are required. See the Memory Map section for more details.

## DIGITAL OUTPUTS

The AD9628 output drivers can be configured to interface with either 1.8 V CMOS or 1.8 V LVDS logic families. The default output mode is CMOS, with each channel output on separate busses as shown in Figure 2.

In CMOS output mode, the CMOS output drivers are sized to provide sufficient output current to drive a wide variety of logic families. However, large drive currents tend to cause current glitches on the supplies and may affect converter performance.

Applications requiring the ADC to drive large capacitive loads or large fanouts may require external buffers or latches.

The CMOS output can also be configured for interleaved CMOS output mode via the SPI port. In interleaved CMOS mode, the data for both channels is output onto a single output bus to reduce the total number of traces required. The timing diagram for interleaved CMOS output mode is shown in Figure 3.

The interleaved CMOS output mode is enabled globally onto both output channels via Bit 5 in Register 0x14. The unused channel output can be disabled by selecting the appropriate bit (Bit 1 or Bit 0) in Register 0x05 and then writing a 1 to the local (channel-specific) output port disable bit (Bit 4) in Register 0x14.

The output data format can be selected to be either offset binary or twos complement by setting the SCLK/DFS pin when operating in the external pin mode (see Table 13).

As detailed in the AN-877 Application Note, *Interfacing to High Speed ADCs via SPI*, the data format can be selected for offset binary, twos complement, or Gray code when using the SPI control.

**Table 13. SCLK/DFS Mode Selection (External Pin Mode)**

Voltage at Pin	SCLK/DFS	SDIO/DCS
AGND	Offset binary (default)	DCS disabled
DRVDD	Twos complement	DCS enabled (default)

## Digital Output Enable Function (OEB)

The AD9628 has a flexible three-state ability for the digital output pins. The three-state mode is enabled through the SPI interface and can subsequently be controlled using the OEB pin or through the SPI. Once enabled via the SPI (Bit 7) in Register 0x101, and the OEB pin is low, the output data drivers and DCOs are enabled. If the OEB pin is high, the output data drivers and DCOs are placed in a high impedance state. This OEB function is not intended for rapid access to the data bus. Note that OEB is referenced to the digital output driver supply (DRVDD) and should not exceed that supply voltage.

When using the SPI interface, the data outputs and DCO of each channel can be independently three-stated by using the output port disable bit (Bit 4) in Register 0x14.

## TIMING

The AD9628 provides latched data with a pipeline delay of 16 clock cycles. Data outputs are available one propagation delay ( $t_{pd}$ ) after the rising edge of the clock signal.

Minimize the length of the output data lines and loads placed on them to reduce transients within the AD9628. These transients can degrade converter dynamic performance.

The lowest typical conversion rate of the AD9628 is 10 MSPS. At clock rates below 10 MSPS, dynamic performance can degrade.

## Data Clock Output (DCO)

The AD9628 provides two data clock output (DCO) signals intended for capturing the data in an external register. In CMOS output mode, the data outputs are valid on the rising edge of DCO, unless the DCO clock polarity has been changed via the SPI. In LVDS output mode, the DCO and data output switching edges are closely aligned. Additional delay can be added to the DCO output using SPI Register 0x17 to increase the data setup time. In this case, the Channel A output data is valid on the rising edge of DCO, and the Channel B output data is valid on the falling edge of DCO. See Figure 2, Figure 3, and Figure 4 for a graphical timing description of the output modes.

**Table 14. Output Data Format**

Input (V)	Condition (V)	Offset Binary Output Mode	Twos Complement Mode	OR
VIN+ – VIN–	< –VREF – 0.5 LSB	0000 0000 0000	1000 0000 0000	1
VIN+ – VIN–	= –VREF	0000 0000 0000	1000 0000 0000	0
VIN+ – VIN–	= 0	1000 0000 0000	0000 0000 0000	0
VIN+ – VIN–	= +VREF – 1.0 LSB	1111 1111 1111	0111 1111 1111	0
VIN+ – VIN–	> +VREF – 0.5 LSB	1111 1111 1111	0111 1111 1111	1

## BUILT-IN SELF-TEST (BIST) AND OUTPUT TEST

The [AD9628](#) includes a built-in test feature designed to enable verification of the integrity of each channel, as well as to facilitate board level debugging. A built-in self-test (BIST) feature that verifies the integrity of the digital datapath of the [AD9628](#) is included. Various output test options are also provided to place predictable values on the outputs of the [AD9628](#).

### BUILT-IN SELF-TEST (BIST)

The BIST is a thorough test of the digital portion of the selected [AD9628](#) signal path. Perform the BIST test after a reset to ensure that the part is in a known state. During BIST, data from an internal pseudorandom noise (PN) source is driven through the digital datapath of both channels, starting at the ADC block output. At the datapath output, CRC logic calculates a signature from the data. The BIST sequence runs for 512 cycles and then stops. Once completed, the BIST compares the signature results with a predetermined value. If the signatures match, the BIST sets Bit 0 of Register 0x24, signifying the test passed. If the BIST test fails, Bit 0 of Register 0x24 is cleared. The outputs are connected during this test, so the PN sequence can be observed as it runs. Writing the value 0x05 to Register 0x0E runs the BIST. This enables Bit 0 (BIST enable) of Register 0x0E and resets the PN sequence generator, Bit 2 (initialize BIST sequence) of Register 0x0E. At the completion of the BIST, Bit 0 of Register 0x24 is automatically cleared. The PN sequence can be continued from its last value by writing a 0 in Bit 2 of Register 0x0E. However, if the PN sequence is not reset, the signature calculation does not equal the predetermined value at the end of the test. At that point, the user must rely on verifying the output data.

### OUTPUT TEST MODES

The output test options are described in Table 18 at Address 0x0D. When an output test mode is enabled, the analog section of the ADC is disconnected from the digital back-end blocks and the test pattern is run through the output formatting block. Some of the test patterns are subject to output formatting, and some are not. The PN generators from the PN sequence tests can be reset by setting Bit 4 or Bit 5 of Register 0x0D. These tests can be performed with or without an analog signal (if present, the analog signal is ignored), but they do require an encode clock. For more information, see the [AN-877](#) Application Note, *Interfacing to High Speed ADCs via SPI*.

## SERIAL PORT INTERFACE (SPI)

The AD9628 serial port interface (SPI) allows the user to configure the converter for specific functions or operations through a structured register space provided inside the ADC. The SPI gives the user added flexibility and customization, depending on the application. Addresses are accessed via the serial port and can be written to or read from via the port. Memory is organized into bytes that can be further divided into fields, which are documented in the Memory Map section. For detailed operational information, see the AN-877 Application Note, *Interfacing to High Speed ADCs via SPI*.

### CONFIGURATION USING THE SPI

Three pins define the SPI of this ADC: the SCLK/DFS pin, the SDIO/DCS pin, and the CSB pin (see Table 15). The SCLK/DFS (a serial clock) is used to synchronize the read and write data presented from and to the ADC. The SDIO/DCS (serial data input/output) is a dual-purpose pin that allows data to be sent to and read from the internal ADC memory map registers. The CSB (chip select bar) is an active low control that enables or disables the read and write cycles.

**Table 15. Serial Port Interface Pins**

Pin	Function
SCLK	Serial clock. The serial shift clock input, which is used to synchronize serial interface reads and writes.
SDIO	Serial data input/output. A dual-purpose pin that typically serves as an input or an output, depending on the instruction being sent and the relative position in the timing frame.
CSB	Chip select bar. An active low control that gates the read and write cycles.

The falling edge of the CSB, in conjunction with the rising edge of the SCLK, determines the start of the framing. An example of the serial timing and its definitions can be found in Figure 62 and Table 5.

Other modes involving the CSB are available. The CSB can be held low indefinitely, which permanently enables the device; this is called streaming. The CSB can stall high between bytes to allow for additional external timing. When CSB is tied high, SPI functions are placed in high impedance mode. This mode turns on any SPI pin secondary functions.

During an instruction phase, a 16-bit instruction is transmitted. Data follows the instruction phase, and its length is determined by the W0 and W1 bits.

In addition to word length, the instruction phase determines whether the serial frame is a read or write operation, allowing the serial port to be used both to program the chip and to read the contents of the on-chip memory. The first bit of the first byte in a multibyte serial data transfer frame indicates whether a read command or a write command is issued. If the instruction is a readback operation, performing a readback causes the serial data input/output (SDIO) pin to change direction from an input to an output at the appropriate point in the serial frame.

All data is composed of 8-bit words. Data can be sent in MSB-first mode or in LSB-first mode. MSB first is the default on power-up and can be changed via the SPI port configuration register. For more information about this and other features, see the AN-877 Application Note, *Interfacing to High Speed ADCs via SPI*.

Figure 62. Serial Port Interface Timing Diagram

## HARDWARE INTERFACE

The pins described in Table 15 comprise the physical interface between the user programming device and the serial port of the AD9628. The SCLK pin and the CSB pin function as inputs when using the SPI interface. The SDIO pin is bidirectional, functioning as an input during write phases and as an output during readback.

The SPI interface is flexible enough to be controlled by either FPGAs or microcontrollers. One method for SPI configuration is described in detail in the AN-812 Application Note, *Microcontroller-Based Serial Port Interface (SPI) Boot Circuit*.

The SPI port should not be active during periods when the full dynamic performance of the converter is required. Because the SCLK signal, the CSB signal, and the SDIO signal are typically asynchronous to the ADC clock, noise from these signals can degrade converter performance. If the on-board SPI bus is used for other devices, it may be necessary to provide buffers between this bus and the AD9628 to prevent these signals from transitioning at the converter inputs during critical sampling periods.

Some pins serve a dual function when the SPI interface is not being used. When the pins are strapped to DRVDD or ground during device power-on, they are associated with a specific function. Table 16 describes the strappable functions supported on the AD9628.

## CONFIGURATION WITHOUT THE SPI

In applications that do not interface to the SPI control registers, the SDIO/DCS pin, the SCLK/DFS pin, and the PDWN pin serve as standalone CMOS-compatible control pins. When the device is powered up, it is assumed that the user intends to use the pins as static control lines for the duty cycle stabilizer, output data format, and power-down feature control. In this mode, the CSB chip select bar should be connected to AVDD, which disables the serial port interface.

When the device is in SPI mode, the PDWN and OEB Pins (if enabled) remain active. For SPI control of output enable and power-down, the OEB and PDWN pins should be set to their default states.

**Table 16. Mode Selection**

Pin	External Voltage	Configuration
SDIO/DCS	DRVDD (default)	Duty cycle stabilizer enabled
	AGND	Duty cycle stabilizer disabled
SCLK/DFS	DRVDD	Twos complement enabled
	AGND (default)	Offset binary enabled
OEB	DRVDD	Outputs in high impedance
	AGND (default)	Outputs enabled
PDWN	DRVDD	Chip in power-down or standby
	AGND (default)	Normal operation

## SPI ACCESSIBLE FEATURES

Table 17 provides a brief description of the general features that are accessible via the SPI. These features are described in detail in the AN-877 Application Note, *Interfacing to High Speed ADCs via SPI*. The AD9628 part-specific features are described in detail following Table 18, the external memory map register table.

**Table 17. Features Accessible Using the SPI**

Feature Name	Description
Mode	Allows the user to set either power-down mode or standby mode
Clock	Allows the user to access the DCS, set the clock divider, set the clock divider phase, and enable the sync
Offset	Allows the user to digitally adjust the converter offset
Test I/O	Allows the user to set test modes to have known data on output bits
Output Mode	Allows the user to set the output mode including LVDS
Output Phase	Allows the user to set the output clock polarity
Output Delay	Allows the user to vary the DCO delay

## MEMORY MAP

### READING THE MEMORY MAP REGISTER TABLE

Each row in the memory map register table has eight bit locations. The memory map is roughly divided into three sections: the chip configuration registers (Address 0x00 to Address 0x02); the channel index and transfer registers (Address 0x05 and Address 0xFF) and the ADC functions registers, including setup, control, and test (Address 0x08 to Address 0x102).

The memory map register table (see Table 18) lists the default hexadecimal value for each hexadecimal address shown. The column with the heading Bit 7 (MSB) is the start of the default hexadecimal value given. For example, Address 0x05, the device index register, has a hexadecimal default value of 0x03. This means that in Address 0x05 Bits[7:2] = 0, and Bits[1:0] = 1. This setting is a default channel index setting. The default value results in both ADC channels receiving the next write command. For more information on this function and others, see the [AN-877](#) Application Note, *Interfacing to High Speed ADCs via SPI*. This application note details the functions controlled by Register 0x00 to Register 0xFF. The remaining registers are documented in the Memory Map Register Description section.

#### Open Locations

All address and bit locations that are not included in Table 18 are not currently supported for this device. Unused bits of a valid address location should be written with 0s. Writing to these locations is required only when part of an address location is open (for example, Address 0x05). If the entire address location

is open (for example, Address 0x13), this address location should not be written to.

#### Default Values

After the [AD9628](#) is reset, critical registers are loaded with default values. The default values for the registers are given in the memory map register table, Table 18.

#### Logic Levels

An explanation of logic level terminology follows:

- “Bit is set” is synonymous with “bit is set to Logic 1” or “writing Logic 1 for the bit.”
- “Clear a bit” is synonymous with “bit is set to Logic 0” or “writing Logic 0 for the bit.”

#### Channel-Specific Registers

Some channel setup functions, such as the signal monitor thresholds, can be programmed differently for each channel. In these cases, channel address locations are internally duplicated for each channel. These registers and bits are designated in Table 18 as local. These local registers and bits can be accessed by setting the appropriate Channel A or Channel B bits in Register 0x05. If both bits are set, the subsequent write affects the registers of both channels. In a read cycle, only Channel A or Channel B should be set to read one of the two registers. If both bits are set during an SPI read cycle, the part returns the value for Channel A. Registers and bits designated as global in Table 18 affect the entire part or the channel features for which independent settings are not allowed between channels.

# AD9628

## MEMORY MAP REGISTER TABLE

All address and bit locations that are not included in Table 18 are not currently supported for this device.

**Table 18. Memory Map Registers**

Addr (Hex)	Register Name	Bit 7 (MSB)	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0 (LSB)	Default Value (Hex)	Comments
Chip Configuration Registers											
0x00	SPI port config (global)	Open	LSB first	Soft reset	1	1	Soft reset	LSB first	Open	0x18	The nibbles are mirrored so LSB-first mode or MSB-first mode registers correctly, regardless of shift mode
0x01	Chip ID (global)	8-bit chip ID[7:0] AD9628 = 0x89								Read only	Unique Chip ID used to differentiate devices; read only
0x02	Chip grade (global)	Open	Speed grade ID 100 = 105 MSPS 101 = 125 MSPS			Open				Read only	Unique speed grade ID used to differentiate devices; read only
Channel Index and Transfer Registers											
0x05	Device index (global)	Open	Open	Open	Open	Open	Open	Data Channel B	Data Channel A	0x03	Bits are set to determine which device on the chip receives the next write command; applies to local registers only
0xFF	Transfer (global)	Open	Open	Open	Open	Open	Open	Open	Transfer	0x00	Synchronously transfers data from the master shift register to the slave
ADC Functions

## MEMORY MAP REGISTER DESCRIPTIONS

For additional information about functions controlled in Register 0x00 to Register 0xFF, see the [AN-877](#) Application Note, *Interfacing to High Speed ADCs via SPI*.

### Power Modes (Register 0x08)

#### Bits[7:6]—Open

#### Bit 5—External Power-Down Pin Function

If set, the external PDWN pin initiates power-down mode. If clear, the external PDWN pin initiates standby mode.

#### Bits[4:2]—Open

#### Bits[1:0]—Internal Power-Down Mode

In normal operation (Bits[1:0] = 00), both ADC channels are active.

In power-down mode (Bits[1:0] = 01), the digital data path clocks are disabled while the digital data path is reset. Outputs are disabled.

In standby mode (Bits[1:0] = 10), the digital data path clocks and the outputs are disabled.

During a digital reset (Bits[1:0] = 11), the digital data path clocks are disabled while the digital data path is held in reset. The outputs are enabled in this state. For optimum performance, it is recommended that both ADC channels be reset simultaneously. This is accomplished by ensuring that both channels are selected via Register 0x05 prior to issuing the digital reset instruction.

### Enhancement Control (Register 0x0C)

#### Bits[7:3]—Open

#### Bit 2—Chop Mode

For applications that are sensitive to offset voltages and other low frequency noise, such as homodyne or direct-conversion receivers, chopping in the first stage of the AD9628 is a feature that can be enabled by setting Bit 2. In the frequency domain, chopping translates offsets and other low frequency noise to  $f_{CLK}/2$  where it can be filtered.

#### Bits[1:0]—Open

#### Output Mode (Register 0x14)

#### Bits[7:6]—Output Port Logic Type

00 = CMOS, 1.8 V

10 = LVDS, ANSI

11 = LVDS, reduced range

#### Bit 5—Output Interleave Enable

For LVDS outputs, setting Bit 5 enables interleaving. Channel A is sent coincident with a high DCO clock, and Channel B is coincident with a low DCO clock. Clearing Bit 5 disables the

interleaving feature. Channel A is sent on least significant bits (LSBs), and Channel B is sent on most significant bits (MSBs). The even bits are sent coincident with a high DCO clock, and the odd bits are sent coincident with a low DCO clock.

For CMOS outputs, setting Bit 5 enables interleaving in CMOS DDR mode. On ADC Output Port A, Channel A is sent coincident with a low DCO clock, and Channel B is coincident with a high DCO clock. On ADC Output Port B, Channel B is sent coincident with a low DCO clock, and Channel A is coincident with a high DCO clock. Clearing Bit 5 disables the interleaving feature, and data is output in CMOS SDR mode. Channel A is sent to Port A, and Channel B is sent to Port B.

#### Bit 4—Output Port Disable

Setting Bit 4 high disables the output port for the channels selected in Bits[1:0] of the device index register (Register 0x05).

#### Bit 3—Open

#### Bit 2—Output Invert

Setting Bit 2 high inverts the output port data for the channels selected in Bits[1:0] of the device index register (Register 0x05).

#### Bits[1:0]—Output Format

00 = offset binary

01 = twos complement

10 = Gray code

### Sync Control (Register 0x3A)

#### Bits[7:3]—Open

#### Bit 2—Clock Divider Next Sync Only

If the clock divider sync enable bit (Address 0x3A, Bit 1) is high, Bit 2 allows the clock divider to sync to the first sync pulse it receives and to ignore the rest. The clock divider sync enable bit resets after it syncs.

#### Bit 1—Clock Divider Sync Enable

Bit 1 gates the sync pulse to the clock divider. The sync signal is enabled when Bit 1 is high. This is continuous sync mode.

#### Bit 0—Open

### Transfer (Register 0xFF)

All registers except Register 0x100 are updated the moment they are written. Setting Bit 0 of this transfer register high initializes the settings in the ADC sample rate override register (Address 0x100).

### Sample Rate Override (Register 0x100)

This register is designed to allow the user to downgrade the device. Any attempt to upgrade the default speed grade results in a chip power-down. Settings in this register are not initialized until Bit 0 of the transfer register (Register 0xFF) is written high.

# AD9628

## ***User I/O Control 2 (Register 0x101)***

### **Bit 7—OEB Pin Enable**

If the OEB pin enable bit (Bit 7) is set, the OEB pin is enabled.

If Bit 7 is clear, the OEB pin is disabled (default).

### **Bits[6:1]—Open**

### **Bit 0—SDIO Pull-Down**

Bit 0 can be set to disable the internal 30 k $\Omega$  pull-down on the SDIO pin, which can be used to limit the loading when many devices are connected to the SPI bus.

## ***User I/O Control 3 (Register 0x102)***

### **Bits[7:4]—Open**

### **Bit 3—VCM Power-Down**

Bit 3 can be set high to power down the internal VCM generator. This feature is used when applying an external reference.

### **Bits[2:0]—Open**

## APPLICATIONS INFORMATION

### DESIGN GUIDELINES

Before starting design and layout of the [AD9628](#) as a system, it is recommended that the designer become familiar with these guidelines, which discuss the special circuit connections and layout requirements that are needed for certain pins.

#### **Power and Ground Recommendations**

When connecting power to the [AD9628](#), it is recommended that two separate 1.8 V supplies be used. Use one supply for analog (AVDD); use a separate supply for the digital outputs (DRVDD). For both AVDD and DRVDD, several different decoupling capacitors should be used to cover both high and low frequencies. Place these capacitors close to the point of entry at the PCB level and close to the pins of the part, with minimal trace length.

A single PCB ground plane should be sufficient when using the [AD9628](#). With proper decoupling and smart partitioning of the PCB analog, digital, and clock sections, optimum performance is easily achieved.

#### **LVDS Operation**

The [AD9628](#) defaults to CMOS output mode on power-up. If LVDS operation is desired, this mode must be programmed, using the SPI configuration registers after power-up. When the [AD9628](#) powers up in CMOS mode with LVDS termination resistors (100  $\Omega$ ) on the outputs, the DRVDD current can be higher than the typical value until the part is placed in LVDS mode. This additional DRVDD current does not cause damage to the [AD9628](#), but it should be taken into account when considering the maximum DRVDD current for the part.

To avoid this additional DRVDD current, the [AD9628](#) outputs can be disabled at power-up by taking the PDWN pin high. After the part is placed into LVDS mode via the SPI port, the PDWN pin can be taken low to enable the outputs.

#### **Exposed Paddle Thermal Heat Slug Recommendations**

It is mandatory that the exposed paddle on the underside of the ADC be connected to analog ground (AGND) to achieve the best electrical and thermal performance. A continuous, exposed (no solder mask) copper plane on the PCB should mate to the [AD9628](#) exposed paddle, Pin 0.

The copper plane should have several vias to achieve the lowest possible resistive thermal path for heat dissipation to flow through the bottom of the PCB. These vias should be filled or plugged to prevent solder wicking through the vias, which can compromise the connection.

To maximize the coverage and adhesion between the ADC and the PCB, a silkscreen should be overlaid to partition the continuous plane on the PCB into several uniform sections. This provides several tie points between the ADC and the PCB during the reflow process. Using one continuous plane with no partitions guarantees only one tie point between the ADC and the PCB. For detailed information about packaging and PCB layout of chip scale packages, see the [AN-772](#) Application Note, *A Design and Manufacturing Guide for the Lead Frame Chip Scale Package (LFCSP)*, at [www.analog.com](http://www.analog.com).

#### **VCM**

The VCM pin should be decoupled to ground with a 0.1  $\mu\text{F}$  capacitor.

#### **Reference Decoupling**

The VREF pin should be externally decoupled to ground with a low ESR, 1.0  $\mu\text{F}$  capacitor in parallel with a low ESR, 0.1  $\mu\text{F}$  ceramic capacitor.

#### **SPI Port**

The SPI port should not be active during periods when the full dynamic performance of the converter is required. Because the SCLK, CSB, and SDIO signals are typically asynchronous to the ADC clock, noise from these signals can degrade converter performance. If the on-board SPI bus is used for other devices, it may be necessary to provide buffers between this bus and the [AD9628](#) to keep these signals from transitioning at the converter inputs during critical sampling periods.
