# ZSC31015

RBic<sub>dLite</sub><sup>TM</sup> Analog Output Sensor Signal Conditioner w/ Diagnostic Features

**ZMDI**<sup>®</sup>

The Analog Mixed Signal Company

## Brief Description

The RBic<sub>dLite</sub><sup>TM</sup> is adjustable to nearly all piezo-resistive bridge sensors. Measured and corrected bridge values are provided at the SIG<sup>TM</sup> pin, which can be configured as an analog voltage output or as a one-wire serial digital output.

The digital one-wire interface (OWI) can be used for a simple PC-controlled calibration procedure to program a set of calibration coefficients into an on-chip EEPROM. The calibrated RBic<sub>dLite</sub><sup>TM</sup> and a specific sensor are mated digitally: fast, precise, and without the cost overhead associated with trimming by external devices or laser. Integrated diagnostics functions make the RBic<sub>dLite</sub><sup>TM</sup> particularly well-suited for automotive applications.\*

## Features

- Digital compensation of sensor offset, sensitivity, temperature drift, and non-linearity
- Programmable analog gain and digital gain; accommodates bridges with spans < 1mV/V and high offset
- Many diagnostic features on chip (e.g., EEPROM signature, bridge connection checks, bridge short detection, power loss detection)
- Independently programmable high and low clipping levels
- 24-bit customer ID field for module traceability
- Internal temperature compensation reference (no external components)
- Option for external temperature compensation with addition of single diode
- Output options: rail-to-rail ratiometric analog voltage (12-bit resolution), absolute analog voltage, digital one-wire interface
- Fast power-up to data out response; output available 5ms after power-up
- Current consumption depends on programmed sample rate: 1mA down to 250µA (typical)
- Fast response time: 1ms (typical)
- High voltage protection up to 30V with external JFET

## Benefits

- No external trimming components required
- Simple PC-controlled configuration and calibration via one-wire interface
- High accuracy ( $\pm 0.1\%$  FSO @ -25 to 85°C;  $\pm 0.25\%$  FSO @ -50 to 150°C)
- Single-pass calibration – quick and precise

## Available Support

- Development Kit available
- Multi-Unit Calibrator Kit available
- Support for industrial mass calibration available
- Quick circuit customization possible for large production volumes

## Physical Characteristics

- Wide operation temperature: -50°C to +150°C
- Supply voltage 2.7 to 5.5V; with external JFET, 5.5 to 30V
- Small SOP8 package

## ZSC31015 Application Circuit

\* Not AEC-Q100-qualified.

# ZSC31015

RBic<sub>QI</sub>Lite™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

The Analog Mixed Signal Company

## 1 Electrical Characteristics

### 1.1. Absolute Maximum Ratings

**Table 1.1 Absolute Maximum Ratings**

Parameter	Symbol	Min	Max	Unit
Analog Supply Voltage	V <sub>DD</sub>	-0.3	6.0	V
Voltages at Analog I/O – In Pin	V <sub>INA</sub>	-0.3	V <sub>DD</sub> +0.3	V
Voltages at Analog I/O – Out Pin	V <sub>OUTA</sub>	-0.3	V <sub>DD</sub> +0.3	V
Storage Temperature Range (≥10 hours)	T <sub>STOR</sub>	-50	150	°C
Storage Temperature Range (<10 hours)	T <sub>STOR &lt;10h</sub>	-50	170	°C

Note: Also see Table 6.1 regarding soldering temperature and storage conditions.

### 1.2. Recommended Operating Conditions

**Table 1.2 Recommended Operating Conditions**

Parameter	Symbol	Min	Typ	Max	Unit
Analog Supply Voltage to Ground	V <sub>DD</sub>	2.7	5.0	5.5	V
Analog Supply Voltage (with external JFET Regulator)	V <sub>SUPP</sub>	5.5	7	30	V
Common Mode Voltage	V <sub>CM</sub>	1		V <sub>DDA</sub> - 1.3	V
Ambient Temperature Range <sup>1,2</sup>	T <sub>AMB</sub>	-50		150	°C
External Capacitance between V <sub>DD</sub> and Ground	C <sub>VDD</sub>	100	220	470	nF
Output Load Resistance to V <sub>SS</sub> or V <sub>DD</sub> <sup>3</sup>	R <sub>L,OUT</sub>	5			kΩ
Output Load Capacitance <sup>4</sup>	C <sub>L,OUT</sub>		10	15	nF
Bridge Resistance <sup>5</sup>	R <sub>BR</sub>	0.2		100	kΩ
Power-On Rise Time	t <sub>PON</sub>			100	ms

<sup>1)</sup> Note that the maximum EEPROM programming temperature is 85°C.

<sup>2)</sup> If buying die, designers should use caution not to exceed maximum junction temperature by proper package selection.

<sup>3)</sup> Only needed for Analog Output Mode; not needed for Digital Output Mode. When a pull-down resistor is used as load resistor, the power loss detection diagnostic for loss of V<sub>SS</sub> cannot be assured at R<sub>L</sub>=5k; R<sub>L</sub>=10k is recommended for this configuration.

<sup>4)</sup> Using the output for digital calibration, C<sub>L,OUT</sub> is limited by the maximum rise time T<sub>ZACrise</sub>. See section 1.3.

<sup>5)</sup> Note: Minimum bridge resistance is only a factor if using the Bsink feature. The R<sub>DS(ON)</sub> of the Bsink transistor is 8 to 10Ω when operating at V<sub>DD</sub>=5V. This does give rise to a ratiometricity inaccuracy that becomes greater with low bridge resistances.

# ZSC31015

RBic<sub>QdLite</sub>™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

The Analog Mixed Signal Company

## 1.3. Electrical Parameters

**Table 1.3 Supply/Regulation Characteristics**

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Supply Voltage	$V_{DD}$		2.7	5.0	5.5	V
Supply Current (varies with update rate and output mode)	$I_{DD}$	At minimum update rate		0.25		mA
		At maximum update rate		1.0	1.4	
Temperature Coefficient – PTAT Source	$T_{CPTAT}$			20	100	ppm/K
Power Supply Rejection Ratio <sup>*</sup>	PSRR		60			dB
Power-On Reset Level	POR		1.4		2.6	V

**Table 1.4 Parameters for Analog Front-End (AFE)**

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Leakage Current Pin VBP, VBN	$I_{IN\_LEAK}$	Sensor connection and short check must be disabled.			±10	nA

**Table 1.5 Parameters for EEPROM**

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Number Write Cycles	$n_{WRI\_EEP}$	At 150°C			100	Cycles
		At 85°C			100k	Cycles
Data Retention	$t_{WRI\_EEP}$	At 100°C			10	Years

**Table 1.6 Parameters for A/D Converter**

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
ADC Resolution	$r_{ADC}$				14	Bit
Integral Nonlinearity (INL) <sup>1</sup>	$INL_{ADC}$	Based on ideal slope	-4		+4	LSB
Differential Nonlinearity (DNL) <sup>*</sup>	$DNL_{ADC}$		-1		+1	LSB

<sup>1)</sup> Note: This is ± 4 LSBs for the 14-bit A-to-D conversion. This results in absolute accuracy to 12-bits on the A-to-D result. Non-linearity is typically better at temperatures less than 125°C.

<sup>\*</sup> No verification in mass production; parameter is guaranteed by design and/or quality observation.

**Table 1.10 Parameters for ZACwire™ Serial Interface**

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
ZACwire™ Line Resistance *	R <sub>ZAC,load</sub>	The rise time must be $T_{ZAC,rise} = 2 * R_{ZAC,load} * C_{ZACload} \leq 5\mu s$ . If using a pull-up resistor instead of a line resistor, it must meet this specification. The absolute maximum for C <sub>ZACload</sub> is 15nF.			3.9	kΩ
ZACwire™ Load Capacitance *	C <sub>ZAC,load</sub>		0	1	15	nF
Voltage Level Low *	V <sub>ZAC,low</sub>			0	0.2	V <sub>DD</sub>
Voltage Level High *	V <sub>ZAC,low</sub>		0.8	1		V <sub>DD</sub>

**Table 1.11 Parameters for System Response**

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Start-Up-Time	t <sub>STA</sub>	Power-up to output Update_rate = 1 kHz (1 ms)			5	ms
Response Time – Analog Output	t <sub>RESP-A</sub>	Update_rate = 1 kHz (1 ms)		1	2	ms
Response and Transmission Time for Digital Output	t <sub>RES, DIG</sub>	Varies with update rate. Value given at fastest rate.		1.6		ms
Sampling Rate	f <sub>s</sub>	Update_rate = 1 kHz (1 ms)		1000		Hz
Overall Linearity Error– Digital	E <sub>LIND</sub>	Bridge input to output		0.025	0.04	%
Overall Linearity Error – Analog	E <sub>LINA</sub>	Bridge input to output		0.1	0.2	%
Overall Ratiometricity Error	RE <sub>out</sub>	±10%VDD, Not using Bsink feature			0.035	%
Overall Accuracy – Digital (only IC, without sensor bridge)	AC <sub>outD</sub>	-25°C to 85°C			±0.1%	%FSO
		-50°C to 150°C			±0.25%	
Overall Accuracy – Analog <sup>1)2)</sup> (only IC, without sensor bridge)	AC <sub>outA</sub>	-25°C to 85°C			±0.25%	%FSO
		-40°C to 125°C			±0.35%	
		-50°C to 150°C			±0.5%	

1) Not included is the quantization noise of the DAC. The 12-bit DAC has a quantization noise of  $\pm \frac{1}{2} \text{ LSB} = 0.61\text{mV} (@ 5\text{V VDD}) = 0.0125\%$ .

2) Analog output range 2.5% to 95%

# ZSC31015

RBic<sub>dLite</sub>™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

The Analog Mixed Signal Company

## 1.4. Analog Inputs versus Output Resolution

The RBic<sub>dLite</sub>™ has a fully differential chopper-stabilized pre-amplifier with 4 programmable gain settings. The output of the pre-amplifier feeds into a 14-bit charge-balanced ADC. Span, offset, temperature, and non-linearity correction are performed in the digital domain. Then the resulting corrected bridge value can be output in analog form through a 12-bit DAC or as a 16-bit serial digital packet. The resolution of the output depends on the input span (bridge sensitivity) and the analog gain setting programmed. Digital gains can vary from [0,32). Analog gains available are 6, 24, 48, and 96.

Note: At higher analog gain settings, there will be higher output resolution, but the ability of the RBic<sub>dLite</sub>™ to handle large offsets decreases. This is expected because the offset is also amplified by the analog gain and can therefore saturate the ADC input.

The following tables outline the guaranteed minimum resolution for a given bridge sensitivity range.

**Table 1.12 ADC Resolution Characteristics for an Analog Gain of 6**

Analog Gain 6				
Input Span [mV/V]			Allowed Offset (+/- % of Span) <sup>1</sup>	Minimum Guaranteed Resolution [Bits]
Min	Typ	Max		
57.8	80.0	105.8	38%	12.4
50.6	70.0	92.6	53%	12.2
43.4	60.0	79.4	73%	12.0
36.1	50.0	66.1	101%	11.7
28.9	40.0	52.9	142%	11.4
21.7	30.0	39.7	212%	11.4

<sup>1)</sup> In addition to Tco, Tcg.

**Table 1.13 ADC Resolution Characteristics for an Analog Gain of 24**

Analog Gain 24				
Input Span [mV/V]			Allowed Offset (+/- % of Span) <sup>1</sup>	Minimum Guaranteed Resolution [Bits]
Min	Typ	Max		
18.1	25.0	33.1	17%	12.7
14.5	20.0	26.5	38%	12.4
7.2	10.0	13.2	142%	11.4
3.6	5.0	6.6	351%	10.4
1.8	2.5	3.3	767%	9.4
0.9	1.2	1.6	1670%	8.4

<sup>1)</sup> In addition to Tco, Tcg. **Important Note:** The yellow shadowed fields indicate that for these input spans with the selected analog gain setting, the quantization noise is higher than 0.1% FSO.

RBic<sub>dLite</sub>™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

The Analog Mixed Signal Company

## 2 Circuit Description

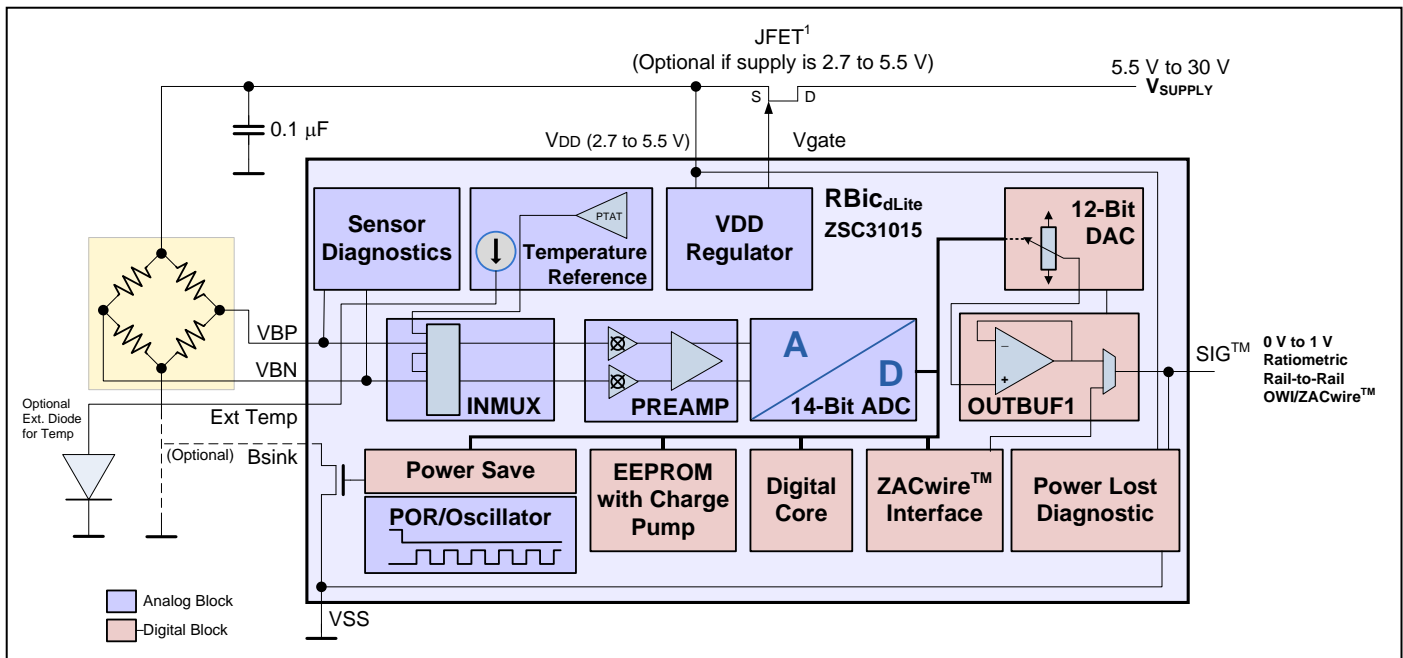

### 2.1. Signal Flow and Block Diagram

The RBic<sub>dLite</sub>™ series of resistive bridge sensor interface ICs were specifically designed as cost-effective solutions for sensing in building automation, automotive<sup>†</sup>, industrial, office automation and white goods applications. The RBic<sub>dLite</sub>™ employs ZMDI's high precision bandgap with proportional-to-absolute-temperature (PTAT) output; low-power 14-bit analog-to-digital converter (ADC, A2D, A-to-D); and an on-chip DSP core with EEPROM to precisely calibrate the bridge output signal.

Three selectable outputs, two analog and one digital, offer the ultimate in versatility across many applications. The RBic<sub>dLite</sub>™ rail-to-rail ratiometric analog  $V_{out}$  signal (0V to ~5 V  $V_{out}$  @  $V_{DD}=5V$ ) suits most building automation and automotive requirements (12-bit resolution). Typical office automation and white goods applications require the 0 to ~1V  $V_{out}$  signal, which in the RBic<sub>dLite</sub>™ is referenced to the internal bandgap. RBic<sub>dLite</sub>™ is capable of running in high-voltage (5.5-30V) systems when combined with an external JFET.

Direct interfacing to  $\mu P$  controllers is facilitated via ZMDI's single-wire serial ZACwire™ digital interface.

## 2.2. Analog Front End

### 2.2.1. Bandgap/PTAT and PTAT Amplifier

The highly linear Bandgap/PTAT section provides the PTAT signal to the ADC, which allows accurate temperature conversion. In addition, the ultra-low ppm Bandgap provides a stable voltage reference over temperature for the operation of the rest of the IC. If the bridge is not near the RBic<sub>dLite</sub><sup>™</sup>, an external diode can be used for temperature measurement/compensation.

The temperature signal (internal PTAT or external diode) is amplified through a path in the Pre-Amp and fed to the ADC for conversion. The most significant 12-bits of this converted result are used for temperature measurement and temperature correction of bridge readings. When temperature is output in Digital Mode, only the most significant 8 bits are given.

When external temperature is selected, add a diode from the ExtTemp pin to ground. The diode is biased with approximately 50µA during temperature measurement cycles. The voltage level on ExtTemp is amplified through the Pre-Amp and converted by the ADC. Ensure that the ExtTemp signal is in the range of 150mV to 800mV to prevent saturation of the ADC. If the selected diode has a sensitivity in the range of 1.9mV/°C to 3.25mV/°C, a corrected temperature output (in Digital Mode) can be achieved for a 200°C temperature span (-50°C to 150°C).

### 2.2.2. Bridge Supply

The voltage-driven bridge is usually connected to V<sub>DD</sub> and ground. As a power savings feature, the RBic<sub>dLite</sub><sup>™</sup> also includes a switched transistor to interrupt the bridge current via pin 1 (Bsink). The transistor switching is synchronized to the analog-to-digital conversion and released after finishing the conversion. To utilize this feature, the low supply of the bridge should be connected to Bsink instead of ground.

Depending on the programmable update rate, the average current consumption (including bridge current) can be reduced to approximately 20%, 5% or 1%. Note: this feature has no power savings benefit if using the fastest update rate mode.

### 2.2.3. PREAMP Block

The differential signal from the bridge is amplified through a chopper-stabilized instrumentation amplifier with very high input impedance designed for low noise and low drift. This pre-amp provides gain for the differential signal and re-centers its DC to V<sub>DD</sub>/2. The output of the Pre-Amp block is fed into the ADC. The calibration sequence performed by the digital core includes an auto-zero sequence to null any drift in the Pre-Amp state over temperature.

The Pre-Amp can be set to a gain of 6, 24, 48 or 96 through EEPROM.

The inputs to the Pre-Amp from (VBN/VBP pins) can be reversed via an EEPROM configuration bit.

## 2.2.4. Analog-to-Digital Converter (ADC)

A 14-bit/1ms 2<sup>nd</sup> order charge-balancing ADC is used to convert signals coming from the pre-amplifier. The converter, designed in full differential switched capacitor technique, is used for converting the various signals in the digital domain.

This principle offers the following advantages:

- High noise immunity because of the differential signal path and integrating behavior
- Independence from clock frequency drift and clock jitter
- Fast conversion time due to second order mode

Four selectable values for the zero point of the input voltage allow conversion to adapt to the sensor's offset parameter. With the Reverse Input Polarity Mode and the negative digital gain options, this results in seven possible zero point adjustments (not eight because the -1/2, 1/2 offset setting is the same regardless of gain polarity).

The conversion rate varies with the programmed update rate. The fastest conversation rate is 1k samples/s and the response time is then 1ms. Based on a best fit, the Integral Nonlinearity (INL) is less than 4 LSB<sub>14Bit</sub>.

## 2.3. Digital Signal Processor

A digital signal processor (DSP) is used for processing the converted bridge data as well as performing temperature correction and computing the temperature value for output on the digital channel.

The digital core reads correction coefficients from EEPROM and can correct for the following:

- Bridge Offset
- Bridge Gain
- Variation of Bridge Offset over Temperature (Tco)
- Variation of Bridge Gain over Temperature (Tcg)
- A single second order effect (SOT) (Second Order Term)

The EEPROM contains a single SOT that can be applied to correct one and only one of the following:

- 2<sup>nd</sup> order behavior of bridge measurement
- 2<sup>nd</sup> order behavior of Tco
- 2<sup>nd</sup> order behavior of Tcg

# ZSC31015

RBic<sub>QdLite</sub><sup>TM</sup> Analog Output Sensor Signal Conditioner w/ Diagnostic Features

**ZMDI**<sup>®</sup>

The Analog Mixed Signal Company

If the SOT applies to correcting the bridge reading, then the correction formula for the bridge reading is represented as a two step process as follows:

$$ZB = \text{Gain\_B}(1 + \Delta T * T_{cg}) * (\text{BR\_Raw} - \text{Offset\_B} + \Delta T * T_{co}) \quad (1)$$

$$\text{BR} = ZB(1.25 + \text{SOT} * ZB) \quad (2)$$

Where:

- BR** = Corrected Bridge reading that is output as digital or analog on SIG<sup>TM</sup> pin
- ZB** = Intermediate result in the calculations
- BR\_Raw** = Raw Bridge reading from ADC
- T\_Raw** = Raw Temp reading converted from PTAT signal or external diode
- Gain\_B** = Bridge Gain term
- Offset\_B** = Bridge Offset term
- Tcg** = Temperature Coefficient Gain
- Tco** = Temperature Coefficient Offset
- ΔT** = (T\_Raw - T<sub>SETL</sub>)
- T<sub>SETL</sub>** = T\_Raw reading at which low calibration was performed (typically 25°C)
- SOT** = Second Order Term

**Note** For solving equation (1) the following condition must be met:

$$\text{BR\_Raw} \geq \text{BR} / \text{Gain\_B}$$

If this condition is not met, the analog Pre-Amp Gain must be set to a smaller value because a negative Offset\_B is not supported.

If the **SOT** applies to correcting the 2<sup>nd</sup> order behavior of **Tco**, then the formula for bridge correction is as follows:

$$\text{BR} = \text{Gain\_B}(1 + \Delta T * T_{cg}) * [\text{BR\_Raw} - \text{Offset\_B} + \Delta T(\text{SOT} * \Delta T + T_{co})] \quad (3)$$

If the SOT applies to correcting the 2<sup>nd</sup> order behavior of Tcg, then the formula for bridge correction is as follows:

$$\text{BR} = \text{Gain\_B}[1 + \Delta T(\text{SOT} * \Delta T + T_{cg})] * [\text{BR\_Raw} - \text{Offset\_B} + \Delta T * T_{co}] \quad (4)$$

The bandgap reference gives a very linear PTAT signal, so temperature correction can always simply be accomplished with a linear gain and offset term.

Corrected Temperature Reading:

$$T = \text{Gain\_T}(T\_Raw + \text{Offset\_T}) \quad (5)$$

Where:

**T\_Raw** = Raw Temperature reading converted from PTAT signal or external diode

**Offset\_T** = Offset Coefficient for Temperature

**Gain\_T** = Gain Coefficient for Temperature

### 2.3.1. EEPROM

The EEPROM contains the calibration coefficients for gain and offset, etc., and the configuration bits, such as output mode, update rate, etc. The RBic<sub>dlite</sub><sup>TM</sup> also offers 3 user-programmable storage bytes for module traceability. When programming the EEPROM, an internal charge pump voltage is used; therefore a high voltage supply is not needed. The EEPROM is implemented as a shift register. During an EEPROM read, the contents are shifted 8 bits before each transmission of one byte occurs. The charge pump is internally regulated to 12.5 V, and the programming time is 6ms.

See section 2.6.1 regarding EEPROM signatures for verifying EEPROM integrity.

Note: EEPROM writing can only be performed at temperatures lower than 85°C.

### 2.3.2. One-Wire Interface - ZACwire<sup>TM</sup>

The IC communicates via a one-wire serial interface. There are different commands available for the following:

- Reading the conversion result of the ADC (Get\_BR\_Raw, Get\_T\_Raw)
- Calibration commands
- Reading from the EEPROM (dump of entire contents)
- Writing to the EEPROM (trim setting, configuration, and coefficients)

## 2.4. Output Stage

### 2.4.1. Digital to Analog Converter (Output DAC) with Programmable Clipping Limits

A 12-bit DAC based on sub-ranging resistor strings is used for the digital-to-analog output conversion in the analog ratiometric and absolute analog voltage modes. Options during calibration configure the system to operate in either of these modes. The design allows for excellent testability as well as low power consumption. The DAC allows programming a lower and upper clipping limit for the output signal (analog and digital). The internal 14-bit calculated bridge value is compared against the 14-bit value formed by {11,Up\_Clip\_Lim[6:0],11111} for the upper limit and {00,Low\_Clip\_Lim[6:0],00000} for the lower limit. If the calculated bridge value is higher than the upper limit or less than the lower limit, the analog output value is clipped to this value; otherwise it is output as is.

# ZSC31015

RBic<sub>dLite</sub><sup>TM</sup> Analog Output Sensor Signal Conditioner w/ Diagnostic Features

**ZMDI**<sup>®</sup>

The Analog Mixed Signal Company

**Example for the upper clipping level:** If the Up\_Clip\_Lim[6:0] = 0000000, then the 14-bit value used for clipping threshold is 11000000011111. This is 75.19% of full scale. Since there are 7 bits of upper clipping limit, there are 127 possible values between 75.19% and 100%. Therefore the resolution of the clipping limits 0.195%.

**Example for the lower clipping level:** If the Low\_Clip\_Lim[6:0] = 1111111, then the 14-bit value used for clipping threshold is 00111111100000. This is 24.8% of full scale. Since there are 7 bits of lower clipping limit, there are 127 possible values between 0 and 24.8%. Therefore the resolution of the lower clipping limit is 0.195%.

Figure 2.2 shows the data timing of the DAC output for the update rate setting 00.

**Figure 2.2 DAC Output Timing for Highest Update Rate**

## 2.4.2. Output Buffer

A rail-to-rail op amp configured as a unity gain buffer can drive resistive loads (whether pull-up or pull-down) as low as 5kΩ and capacitances up to 15nF (for pure analog output). In addition, to limit the error due to amplifier offset voltage, an error compensation circuit is included which tracks and reduces offset voltage to < 1mV. The output of the RBic<sub>dLite</sub><sup>TM</sup> output can be permanently shorted to VDD or VSS without damaging the device. The output driver contains a current-limiting block that detects a hard short and limits the current to a safe level. The short circuit protection current can vary from a minimum of 3mA to a maximum of 40mA depending on operating conditions. Output short circuit protection can be enabled via Diag\_cfg (EEPROM [102:100]). Enabling this protection is recommended when using the analog output.

## 2.4.3. Voltage Reference Block

A linear regulator control circuit is included in the Voltage Reference Block to interface with an external JFET to allow operation in systems where the supply voltage exceeds 5.5V. This circuit can also be used for over-voltage protection. The regulator set point has a coarse adjustment controlled by the JFET\_cfg EEPROM bits that can adjust the set point around 5.0 or 5.5V (See Table 3.5 for bit locations and section 2.3.1 regarding writing to the EEPROM.). The 1V trim setting (see below) can also act as a fine adjust for the regulation set point. The 5V reference can be trimmed within +/-15mV.

Note: If using the external JFET for over-voltage protection purposes (i.e., 5V at JFET drain and expecting 5V at JFET source), there will be a voltage drop across the JFET; therefore ratiometricity will be slightly compromised depending on the rds(on) of the chosen JFET. A Vishay J107 is the best choice because it has only an 8mV drop worst case. If using as regulation instead of over-voltage, a MMBF4392 or BSS169 also works well.

The Voltage Reference Block uses the absolute reference voltage provided by the bandgap to produce two regulated on-chip voltage references. A 1V reference is used for the output DAC high reference when the part is

# ZSC31015

RBic<sub>QdLite</sub>™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

**ZMDI**®

The Analog Mixed Signal Company

configured in 0-1V Analog Output Mode. For this reason, the 1V reference must be very accurate and includes trim so that its value can be trimmed within +/- 3mV of 1.00V. The 1V reference is also used as the on-chip reference for the JFET regulator block. The regulation set point of the JFET regulator can be fine tuned using the 1V trim.

The reference trim setting is selected with the 1V\_Trim/JFET\_Trim bits in EEPROM. See Table 3.5 for bit locations. Table 2.1 shows the order of trim codes with 0111 for the lowest reference voltage and 1000 for the highest reference voltage.

**Important:** Optimal reference trim is determined during wafer-level testing and final package testing. Back-up copies of these bits are stored in bits in the CUST\_ID0 bits for applications requiring accurate references. In this case, see section 5 for important notes and instructions for verifying the integrity of the 1V\_Trim/JFET\_Trim bits and if necessary, restoring the value from the CUST\_ID0 bits before calibration.

**Table 2.1** 1V Reference Trim (1V vs. Trim for Nominal Process Run)

Order	1Vref/ 5Vref_trim3	1Vref/ 5Vref_trim2	1Vref/ 5Vref_trim1	1Vref/ 5Vref_trim0
<i>Highest Reference Voltage</i>	1	0	0	0
...	1	0	0	1
...	1	0	1	0
...	1	0	1	1
...	1	1	0	0
...	1	1	0	1
...	1	1	1	0
...	1	1	1	1
...	0	0	0	0

**ZMDI**<sup>®</sup>

The Analog Mixed Signal Company

## 2.5. Clock Generator / Power-On Reset (CLKPOR)

If the power supply exceeds 2.5V (maximum), the reset signal de-asserts and the clock generator starts working at a frequency of approximately 512kHz ( $\pm 20\%$ ). The exact value only influences the conversion cycle time and communication to the outside world but not the accuracy of signal processing. In addition, to minimize the oscillator error as the  $V_{DD}$  voltage changes, an on-chip regulator is used to supply the oscillator block.

### 2.5.1. Trimming the Oscillator

Settings for the Osc\_Trim bits in EEPROM fine-tune the oscillator frequency. See Table 3.5 for bit locations and Table 2.2 for possible settings. The default value is 0<sub>HEX</sub> to ensure communication on start-up.

**Important:** Optimal oscillator trimming is determined during wafer-level testing and final package testing, and this part-specific factory value, which can be copied to Osc\_Trim, is stored in bits in the CUST\_ID1 and CUST\_ID2 EEPROM bits for applications requiring optimal response time. In this case, see section 5 for important notes and instructions for copying these optimal values to the Osc\_Trim bits before calibration. It is strongly recommended that only the default value or the factory trim value be used because ZACwire<sup>TM</sup> communication is not guaranteed at different oscillator frequencies.

**Table 2.2 Oscillator Trimming**

Osc_Trim Bits	Delta Frequency (kHz)
100	+385
101	+235
110	+140
111	+65
000	Nominal
001	-40
010	-76
011	-110

Example: Programming 011<sub>B</sub> → the trimmed frequency = nominal value - 110 kHz.

## 2.6. Diagnostic Features

The RBic<sub>dLite</sub><sup>TM</sup> offers a full suite of diagnostic features to ensure robust system operation in the most “mission-critical” applications. If the part is programmed in Analog Output Mode, then diagnostic states are indicated by an output below 2.5% of VDD or above 97.5% of VDD. If the part is programmed in Digital Output Mode, then diagnostic states will be indicated by a transmission with a generated parity error.

Table 2.3 gives a summary of the diagnostic features, which are explained in detail in the following sections. EEPROM settings that control diagnostic functions are given in section 3.5.

# ZSC31015

RBic<sub>dLite</sub>™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

**ZMDI**®

The Analog Mixed Signal Company

**Table 2.3 Summary of Diagnostic Features**

Detected Fault	Analog Diagnostic Level	ZACwire™ Diagnostic	Delay in Detection
EEPROM signature	Lower	Generates parity error	10ms after power-on
Loss of bridge positive	Upper	Generates parity error	2ms
Loss of bridge negative	Upper	Generates parity error	2ms
Open bridge connection	Upper	Generates parity error	2ms
Bridge input short	Upper	Generates parity error	2ms
ExtTemp pin open	Lower	Generates parity error	300ms
ExtTemp pin shorted to PWR/GND	Lower	Generates parity error	300ms
ExtTemp pin shorted to BP/BN <sup>‡</sup>	Upper	Generates parity error	3ms
Loss of VDD	Lower	Transmissions stop	Dependent on R <sub>L</sub> and C <sub>L</sub>
Loss of VSS	Upper	Transmissions stop	Dependent on R <sub>L</sub> and C <sub>L</sub>

## 2.6.1. EEPROM Integrity

The contents of the EEPROM are protected by an 8-bit LFSR signature (linear feedback shift register). This signature is regenerated and stored in EEPROM every time EEPROM contents are changed. This signature is generated and checked for a match after Power-On-Reset prior to entering Normal Operation Mode. If the generated signature fails to match, the part will output a diagnostic state on the output.

In addition to an extensive temporal and code interlock mechanism used to prevent false writes to the EEPROM, the RBic<sub>dLite</sub>™ offers an EEPROM lock mechanism for high-security applications. When EEPROM bits 105:103 are programmed with “011” or “110,” this 3-bit field will permanently disable the VPP charge pump and will not allow further writes to the EEPROM. See Table 2.3 in section 2.6 for more information.

## 2.6.2. Sensor Connection Check

Four dedicated comparators permanently check the range of the bridge inputs (BP/BN) to ensure they are within the envelope of 0.8V to 0.85\*VDD during all conversions. The two sensor inputs have a switched ohmic path to ground and if left floating, would be discharged. If any of the wires connecting the bridge break, this mechanism will detect it and put the ASIC in a diagnostic state. This same diagnostic feature can also detect a short between BP/BN and the ExtTemp signal if an external diode is being used for temperature measurement. See Table 2.3 in section 2.6 for more information.

<sup>‡</sup> A short from ExtTemp to BP/BN might not be detected in some circuit configurations.

# ZSC31015

RBic<sub>QdLite</sub>™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

**ZMDI**®

The Analog Mixed Signal Company

## 2.6.3. Sensor Short Check

If a short occurs between BP/BN (bridge inputs), it would normally produce an in-range output signal and therefore would not be detected as a fault. This diagnostic mode, if enabled, will deliberately look for such a short. After the measurement cycle of the bridge, it will deliberately pull the BP bridge input to ground for 4 $\mu$ sec. At the end of this 4 $\mu$ sec window, it will check to see if the BN input “followed” it down below the 0.8V comparator checkpoint. If so, a short must exist between BP/BN, and the part will output a diagnostic state. The bridge will have a minimum of 480 $\mu$ sec recovery time prior to the next measurement. See Table 2.3 in section 2.6 for more information.

## 2.6.4. Power Loss Detection

If the power or GND connection to the module containing the sensor bridge and ASIC is lost, the ASIC will output a diagnostic state if a pull-up or pull-down terminating resistor greater than or equal to 5k $\Omega$  is connected in the final application. This diagnostic mode only works when the part is configured in Analog Output Mode. See Table 2.3 in section 2.6 for more information.

## 2.6.5. ExtTemp Connection Checks

When external temperature is selected and connection checking is enabled, the part performs range checking on the converted temperature value. If the internal ADC reading of the temperature is less than 1/32 of full scale or greater than 63/64 of full scale then a diagnostic state is asserted. If the ExtTemp pin is shorted to ground, the ADC reads less than 1/32. Because 100 $\mu$ A is sourced onto the ExtTemp pin during conversions, it naturally pulls up during these times. If the ExtTemp pin is open, it produces an ADC reading greater than 63/64 of full scale. Both these bad connection conditions would be detected and result in a diagnostic output. If internal temperature is selected or sensor connection check is not enabled, then this diagnostic check is not enabled. See Table 2.3 in section 2.6 for more information.

## 3 Functional Description

### 3.1. General Working Mode

The command/data transfer takes place via the one-wire SIG<sup>TM</sup> pin using the ZACwire<sup>TM</sup> serial communication protocol.

After power-on, the IC waits for 3ms (= Command window) for the Start\_CM command.

Without this command, the Normal Operation Mode (NOM) starts. In this mode, raw bridge values are converted, and the corrected values are presented on the output in analog or digital format (depending on the configuration stored in EEPROM).

Command Mode (CM) can only be entered during the 3ms command window after Power ON. If the IC receives the Start\_CM command during the command window, it remains in the Command Mode. The CM allows changing to one of the other modes via command. After command Start\_RW, the IC is in the Raw Mode. Without correction, the raw values are transmitted to the digital output in a predefined order. The RM can only be stopped by Power OFF. Raw Mode is used by the calibration software for collection of raw bridge and temperature data so the correction coefficients can be calculated.

If diagnostic features are enabled and a diagnostic fault is detected, diagnostic states are indicated as follows depending on the programmed mode:

- In Analog Output Mode:  
Diagnostic states are indicated by an output below 2.5% of VDD or above 97.5% of VDD.
- In Digital Output Mode:  
Diagnostic states will be indicated by a transmission with a generated parity error.

For more details see section 2.6.

## 3.2. ZACwire™ Communication Interface

### 3.2.1. Properties and Parameters

**Table 3.1 Pin Configuration and Latch-Up Conditions**

No.	Parameter	Symbol	Min	Typ	Max	Unit	Comments
1	Pull-up resistor (on-chip)	R <sub>ZAC,pu</sub>		30		kΩ	On-chip pull-up resistor switched on during Digital Output Mode and during CM Mode (first 3 ms after power up)
2	Pull-up resistor (external)	R <sub>ZAC,pu_ext</sub>	150			Ω	If the master communicates via a push-pull stage, no pull-up resistor is needed; otherwise, a pull-up resistor with a value of at least 150 Ω must be connected.
3	ZACwire™ rise time	T <sub>ZAC,rise</sub>			5	μs	Any user RC network included in Sig™ path must meet this rise time
4	ZACwire™ line resistance <sup>1)</sup>	R <sub>ZACload</sub>			3.9	kΩ	Also see section 1.3, Table 1.10.
5	ZACwire™ load capacitance <sup>1)</sup>	C <sub>ZAC,load</sub>	0	1	15	nF	Also see section 1.3, Table 1.10.
6	Voltage low level	V <sub>ZAC,low</sub>		0	0.2	V <sub>DD</sub>	Rail-to-rail CMOS driver
7	Voltage high level	V <sub>ZAC,high</sub>	0.8	1		V <sub>DD</sub>	Rail-to-rail CMOS driver

<sup>1)</sup> The rise time must be  $T_{ZAC,rise} = 2 * R_{ZACload} * C_{ZACload} \leq 5 \mu s$ . If using a pull-up resistor instead of a line resistor, it must meet this specification. The absolute maximum for C<sub>ZACload</sub> is 15nF.

### 3.2.2. Bit Encoding

**Figure 3.2 Manchester Duty Cycle**

Start bit = 50% duty cycle used to set up strobe time

Logic 1 = 75% duty cycle

Logic 0 = 25% duty cycle

Stop Time

The ZACWire™ bus will be held high for 32μs (nominal) between consecutive data packets regardless of baud rate.

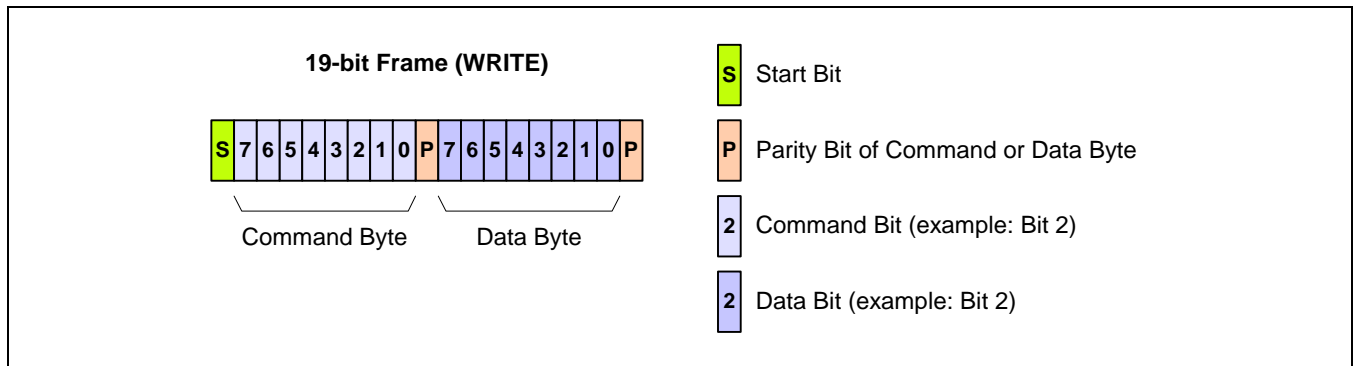

### 3.2.3. Write Operation from Master to RBic<sub>dLite</sub>™

The calibration master sends a 19-bit packet frame to the IC.

**Figure 3.3 19-Bit Write Frame**

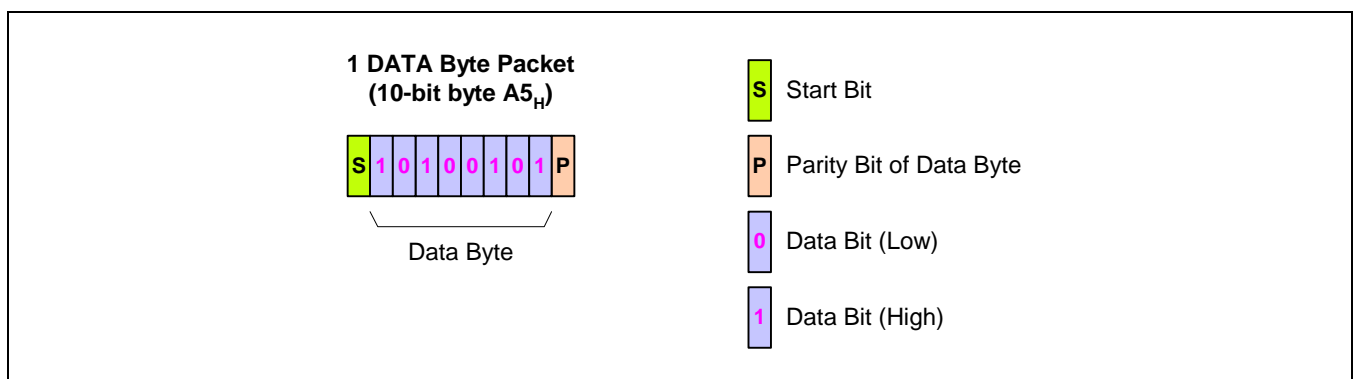

The incoming serial signal will be sampled at a 512 kHz clock rate. This protocol is very tolerant to clock skew, and can easily tolerate baud rates in the 6 kHz to 48 kHz range.

### 3.2.4. RBic<sub>dLite</sub>™ Read Operations

The incoming frame will be checked for proper parity on both, command and data bytes, as well as for any edge time-outs prior to a full frame being received.

Once a command/data pair is received, the RBic<sub>dLite</sub>™ will perform that command. After the command has been successfully executed by the IC, the IC will acknowledge success by a transmission of an A5<sub>H</sub>-byte back to the master. If the master does not receive an A5<sub>H</sub> transmission within 130 ms of issuing the command, it must assume the command was either improperly received or could not be executed.

**Figure 3.4 Read Acknowledge**

The RBic<sub>dLite</sub>™ transmits 10-bit bytes (1 start bit, 8 data bits, 1 parity bit). During calibration and configuration, transmissions are normally either A5<sub>H</sub> or data. A5<sub>H</sub> indicates successful completion of a command. There are two

# ZSC31015

RBic<sub>QdLite</sub>™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

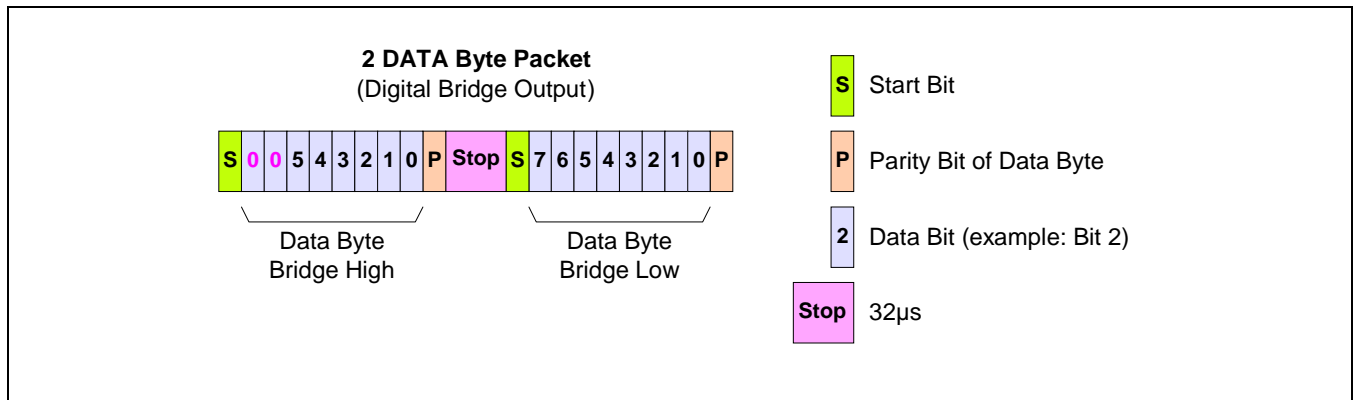

**ZMDI**®

The Analog Mixed Signal Company

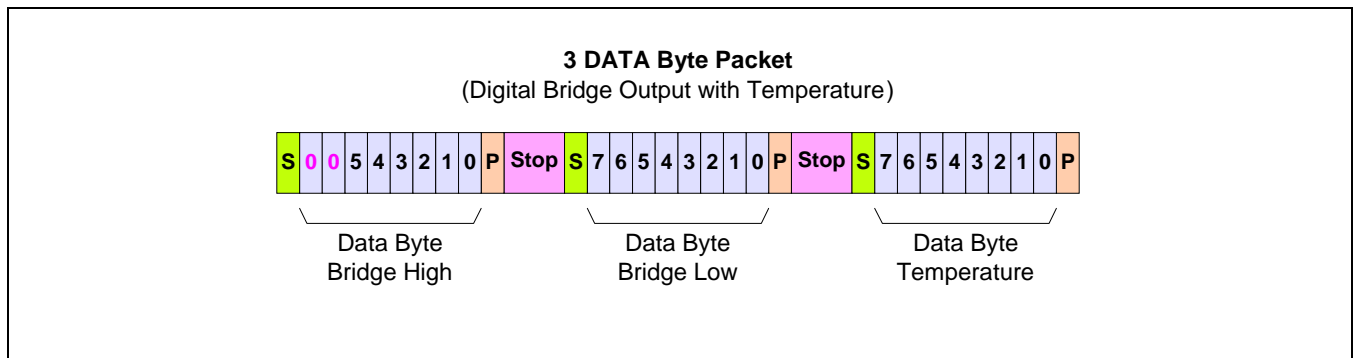

different digital output modes configurable (digital output with temperature, and digital output with only bridge data). During Normal Operation Mode, if the part is configured for digital output of the bridge reading, it first transmits the high byte of bridge data, followed by the low byte. The bridge data is 14 bits in resolution, so the upper two bits of the high byte are always zero-padded. There is a half stop bit time between bytes in a packet. This means that for the time of a half a bit width, the signal level is high.

**Figure 3.5 Digital Output (NOM) Bridge Readings**

The second option for Digital Output Mode is digital output bridge reading with temperature. It will be transmitted as 3 data packets. The temperature byte represents an 8-bit temperature quantity spanning from -50 to 150°C.

**Figure 3.6 Digital Output (NOM) Bridge Readings with Temperature**

The EEPROM transmission occurs in a packet with 20 data bytes, as shown in Figure 3.7.

# ZSC31015

R<sub>Bic</sub>Lite™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

The Analog Mixed Signal Company

**Figure 3.7 Read EEPROM Contents**

There is a variable idle time between packets. This idle time varies with the update rate setting in EEPROM.

**Figure 3.8 Transmission of a Number of Data Packets**

The table below shows the idle time between packets versus the update rate. This idle time can vary by nominal +/-15% between parts and over a temperature range of -50 to 150°C.

**Table 3.2 Special Measurement/Idle Time between Packets versus Update Rate**

Update Rate Setting	Idle Time between Packets	Special Measurement
00	1ms	Every 128 bridge measurements
01	4.85ms	Every 64 bridge measurements
10	22.5ms	Every 16 bridge measurements
11	118ms	Every 8 bridge measurements

Transmissions from the IC occur at one of two speeds depending on the update rate programmed in EEPROM. If the user chooses one of the two fastest update rates (1 ms or 5 ms) then the baud rate of the digital transmission will be 32 kHz (minimum 26kHz). If, however, the user chooses one of the two slower update rates (25 ms or 125 ms), then the baud rate of the digital transmission will be 8 kHz (maximum 9.6kHz).

The total transmission time for both digital output configurations is shown in Table 3.3.

# ZSC31015

RBic<sub>dLite</sub>™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

The Analog Mixed Signal Company

**Table 3.3 Total Transmission Time for Different Update Rate Settings and Output Configuration**

Update Rate	Baud Rate*	Idle Time	Transmission Time – Bridge Only Readings			Transmission Time – Bridge & Temperature Readings		
			20.5 bits	31.30 µs	1.64 ms	31.0 bits	31.30 µs	1.97 ms
1 ms (1 kHz)	32 kHz	1.0 ms	20.5 bits	31.30 µs	1.64 ms	31.0 bits	31.30 µs	1.97 ms
5 ms (200 Hz)	32 kHz	4.85 ms	20.5 bits	31.30 µs	5.49 ms	31.0 bits	31.30 µs	5.82 ms
25 ms (40 Hz)	8 kHz	22.5 ms	20.5 bits	125.00 µs	25.06 ms	31.0 bits	125.00 µs	26.38 ms
125 ms (8 Hz)	8 kHz	118.0 ms	20.5 bits	125.00 µs	120.56 ms	31.0 bits	125.00 µs	121.88 ms

\* Typical values. Minimum baud rate for 1 ms or 5 ms: 26kHz; maximum baud rate for 25 ms or 125 ms: 9.6kHz.

The temperature raw reading is performed less often than a bridge reading, because the temperature changes more slowly.

The 3rd column in Table 3.2 shows the timing for the special measurements (temperature and bridge measurement) in the different update rate modes.

For lower update rates, the output is followed by a power-down as shown in Figure 3.9.

**Figure 3.9 ZACwire™ Output Timing for Lower Update Rates**

It is easy to program any standard microcontroller to communicate with the RBic<sub>dLite</sub>™. ZMDI can provide sample code for a MicroChip PIC microcontroller.

### 3.2.5. High Level Protocol

The RBic<sub>dLite</sub>™ will listen for a command/data pair to be transmitted for the 3 ms after the de-assertion of its internal Power On Reset (POR). If a transmission is not received within this time frame, then it will transition to Normal Operation Mode (NOM). In the NOM, it will output bridge data in 0-1V analog, rail-to-rail ratiometric analog, or digital depending on how the part is currently configured.

If the RBic<sub>dLite</sub>™ receives a Start\_CM command within the first 3 ms after the de-assertion of POR, then it will go into Command Mode (CM). In this mode, calibration/configuration commands will be executed. The RBic<sub>dLite</sub>™ will acknowledge successful execution of commands by transmission of A5H. The calibrating /configuring master will know a command was not successfully executed if no response is received after 130ms of issuing the command. Once in command interpreting/executing mode, the RBic<sub>dLite</sub>™ will stay in this mode until power is removed or a Start NOM (Start Normal Operation Mode) command is received. The Start\_CM command is used as an interlock mechanism to prevent a spurious entry into Command Mode on power up. The first command received within the 3ms window of POR must be a Start\_CM command to enter into command interpreting mode. Any other commands will be ignored.

### 3.3. Command/Data Bytes Encoding

The 2-byte command sent to the RBic<sub>dl</sub>Lite™ consists of 1 byte of command information and 1 byte of data information. Regardless of whether the command requires data or not, 2 bytes MUST be sent. Table 3.4 lists all the command/data pairings. (X=don't care.)

**Table 3.4 Command/Data Bytes Encoding**

Command Byte	Data	Description

### 3.4. Calibration Sequence

Although the RBic<sub>dLite</sub>™ IC can work with many different types of resistive bridges, assume a pressure bridge is being used for the following discussion on calibration.

Calibration essentially involves collecting raw bridge and temperature data from the IC for different known pressures and temperatures. This raw data can then be processed by the calibration master (typically a PC) to compute the coefficients, and the calculated coefficients can then be written to the IC.

ZMDI can provide software and hardware with samples to perform the calibration.

#### There are three main steps to calibration:

1. Assigning a unique identification to the IC. This identification is programmed in EEPROM and can be used as an index into the database stored on the calibration PC. This database will contain all the raw values of bridge readings and temperature readings for that part, as well as the known pressure (for this application) and temperature the bridge was exposed to. This unique identification can be stored in a concatenation of the following EEPROM registers: Cust\_ID0, Cust\_ID1, Cust\_ID2. These registers can also form a permanent serial number.
2. Data collection. Data collection involves getting raw data from the bridge at different known pressures and temperatures. This data is then stored on the calibration PC using the unique identification of the IC as the index to the database.
3. Coefficient calculation and write. Once enough data points have been collected to calculate all the desired coefficients then the coefficients can be calculated by the calibrating PC and written to the IC.

# ZSC31015

RBic<sub>dLite</sub><sup>TM</sup> Analog Output Sensor Signal Conditioner w/ Diagnostic Features

**ZMDI**<sup>®</sup>

The Analog Mixed Signal Company

## Step 1 – Assigning Unique Identification

Assigning a unique identification number is as simple as using the commands Program Cust\_ID0, Program Cust\_ID1 and Program Cust\_ID2. These three 8-bit registers allow for more than 16 million unique devices. Gain\_B must be programmed to 800<sub>H</sub> (unity) and Gain\_T must be programmed to 80H (unity).

## Step 2 – Data Collection

The number of unique (pressure, temperature) points that calibration must be performed at depends on the customer's needs. The minimum is a 2-point calibration, and the maximum is a 5-point calibration. To acquire raw data from the part, set RBic<sub>dLite</sub><sup>TM</sup> to enter Raw Mode. This is done by issuing a Start\_CM (Start Command Mode 5090<sub>H</sub>) command/data pair to the IC followed by a Start\_RM (Start Raw Mode 4010<sub>H</sub>) command/data pair with the LSB of the upper data nibble set. Now if the Gain\_B term has been set to unity (800<sub>H</sub>) and the Gain\_T term has also been set to unity (80H), then the part will be in the Raw Mode and will output raw data on its SIG<sup>TM</sup> pin instead of corrected bridge and temperature. Capture several of these data points with the user's calibration system (16 each of bridge and temperature is recommended) and average them. Store these raw bridge and temperature settings in the database along with the known pressure and temperature. The output format during Raw Mode is Bridge\_High, Bridge\_Low, Temp. Each of these is an 8-bit quantity. The upper 2-bits of Bridge\_High are zero filled. The Temp data (8-bits only) would not be enough information for accurate temperature calibration. Therefore the upper three bits of temperature information are not given, but rather assumed known. Therefore effectively 11-bits of temperature information are provided in this mode.

## Step 3 – Coefficient Calculations

The math to perform the coefficient calculation is very complicated and will not be discussed in detail. There is a rough overview in the "Calibration Math" section. ZMDI will provide software to perform the coefficient calculation. ZMDI can also provide source code for the algorithms in a C code format. After the coefficients are calculated, the final step is to write them to the EEPROM of the RBic<sub>dLite</sub><sup>TM</sup>.

The number of calibration points required can be as few as two or as many as five. This depends on the precision desired and the behavior of the resistive bridge in use.

1. 2-point calibration can be used if only a gain and offset term are needed for a bridge with no temperature compensation for either term.
2. 3-point calibration would be used to obtain 1<sup>st</sup> order compensation for either a Tco or Tcg term but not both.
3. 3-point calibration could also be used to obtain 2<sup>nd</sup> order correction for the bridge but no temperature compensation of the bridge output.
4. 4-point calibration would be used to obtain 1<sup>st</sup> order compensation for both Tco and Tcg.
5. 4-point calibration could also be used to obtain 1<sup>st</sup> order compensation for Tco and a 2<sup>nd</sup> order correction for the bridge measurement.
6. 5-point calibration would be used to obtain both 1<sup>st</sup> order Tco correction and 1<sup>st</sup> order Tcg correction, plus a 2<sup>nd</sup> order correction that could be applied to one and only one of the following: 2<sup>nd</sup> order Tco, 2<sup>nd</sup> order Tcg, or 2<sup>nd</sup> order bridge.

## 3.6. Calibration Math

### 3.6.1. Correction Coefficients

All terms are calculated external to the IC and then programmed to the EEPROM through the serial interface.

**Table 3.6 Correction Coefficients**

Coefficient	Description
<b>Gain_B</b>	Gain term used to compensate span of Bridge reading
<b>Offset_B</b>	Offset term used to compensate offset of Bridge reading
<b>Gain_T</b>	Gain term used to compensate span of Temp reading
<b>Offset_T</b>	Offset term used to compensate offset of Temp reading
<b>SOT</b>	Second Order Term. The SOT can be applied as a second order correction term for one of the following: <ul style="list-style-type: none"> <li>- Bridge measurement</li> <li>- Temperature coefficient of offset (Tco)</li> <li>- Temperature coefficient of gain (Tcg)</li> </ul> The EEPROM bits 99:98 determine what SOT applies to.
<b>T<sub>SETL</sub></b>	RAW_PTAT or ExtTemp reading (upper 7-bits) at low temperature at which calibration was performed (typically room temperature)
<b>Tcg</b>	Temperature correction coefficient of bridge gain term. <i>This term has an 8-bit magnitude and a sign bit (Tc_cfg[2]).</i>
<b>Tco</b>	Temperature correction coefficient of bridge offset term. This term has an 8-bit magnitude, a sign bit (Tc_cfg[0]), and a scaling bit (Tc_cfg[1]), which can multiply its magnitude by 8.

### 3.6.2. Interpretation of Binary Numbers for Correction Coefficients

BR\_Raw should be interpreted as an unsigned number in the set [0, 16383] with a resolution of 1.

T\_Raw should be interpreted as an unsigned number in the set [0, 16383], with a resolution of 4.

# ZSC31015

RBic<sub>qL</sub>ite™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

**ZMDI**®

The Analog Mixed Signal Company

### 3.6.2.1. Gain\_B Interpretation

Gain\_B should be interpreted as a number in the set [0, 64]. The MSB (bit 14) is a scaling bit that will multiply the effect of the Gain\_B[13:0] term by 8. The remaining bits Gain\_B[13:0] represent a number in the range of [0,8] with Gain\_B[13] having a weighting of 4, and each subsequent bit has a weighting of ½ the previous bit.

**Table 3.7 Gain\_B [13:0] Weightings**

Bit Position	Weighting
13	$2^2 = 4$
12	$2^1 = 2$
11	$2^0 = 1$
10	$2^{-1}$
...	...
3	$2^{-8}$
2	$2^{-9}$
1	$2^{-10}$
0	$2^{-11}$

Examples:

The binary number:  $010010100110001_B = 4.6489$ ; Gain\_B[14] is  $0_B$ , so the number represented by Gain\_B[13:0] is not multiplied by 8.

The binary number:  $101100010010110_B = 24.586$ ; Gain\_B[14] is  $1_B$ , so the number represented by Gain\_B[13:0] is multiplied by 8.

### 3.6.2.2. Offset\_B Interpretation

Offset\_B is a 14-bit unsigned binary number. The MSB has a weighting of 8192. The following bits then have a weighting of: 4096, 2048, 1024 ...

**Table 3.8 Offset\_B Weightings**

Bit Position	Weighting
13	8192
12	4096
11	2048
.	
.	
.	
1	$2^1 = 2$
0	$2^0 = 1$

For example, the binary number  $1111\ 1111\ 1100 = 4092$ .

# ZSC31015

RBic<sub>QdLite</sub>™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

**ZMDI**®

The Analog Mixed Signal Company

### 3.6.2.3. Gain\_T Interpretation

Gain\_T should be interpreted as a number in the set [0,2]. Gain\_T[7] has a weighting of 1, and each subsequent bit has a weighting of ½ the previous bit.

**Table 3.9 Gain\_T Weightings**

Bit Position	Weighting
7	$2^0 = 1$
6	$2^{-1} = 0.5$
5	$2^{-2} = 0.25$
4	$2^{-3}$
3	$2^{-4}$
2	$2^{-5}$
1	$2^{-6}$
0	$2^{-7}$

### 3.6.2.4. Offset\_T Interpretation

Offset\_T is an 8-bit signed binary number in two's complement form. The MSB has a weighting of -128. The following bits then have a weighting of 64, 32, 16 ...

**Table 3.10 Offset\_T Weightings**

Bit Position	Weighting
7	-128
6	$2^6 = 64$
5	$2^5 = 32$
4	$2^4 = 16$
3	$2^3 = 8$
2	$2^2 = 4$
1	$2^1 = 2$
0	$2^0 = 1$

For example, the binary number  $00101001_B = 41$ .

# ZSC31015

RBic<sub>QdLite</sub>™ Analog Output Sensor Signal Conditioner w/ Diagnostic Features

**ZMDI**®

The Analog Mixed Signal Company

## 3.6.2.5. Tco Interpretation

Tco is specified as having an 8-bit magnitude with an additional sign bit and a scalar bit (Tc\_cfg). When the scalar bit is set, the signed Tco is multiplied by 8.

- Tco Resolution: 0.175  $\mu\text{V}/\text{V}/^\circ\text{C}$  (input referred)
- Tco Range:  $\pm 44.6 \mu\text{V}/\text{V}/^\circ\text{C}$  (input referred)

If the scaling bit is used, then the above resolution and range are scaled by 8 to give the following results:

- Tco Scaled Resolution: 1.40  $\mu\text{V}/\text{V}/^\circ\text{C}$  (input referred)
- Tco Scaled Range:  $\pm 357 \mu\text{V}/\text{V}/^\circ\text{C}$  (input referred)

## 3.6.2.6. Tcg Interpretation

Tcg is specified as an 8-bit magnitude with an additional sign bit (Tc\_cfg).

- Tcg Resolution: 17.0 ppm/ $^\circ\text{C}$
- Tcg Range:  $\pm 4335 \text{ ppm}/^\circ\text{C}$

## 3.6.2.7. SOT Interpretation

SOT is a 2<sup>nd</sup> order term that can apply to one and only one of the following: bridge non-linearity correction, Tco non-linearity correction, or Tcg non-linearity correction.

As it applies to bridge non-linearity correction:

- Resolution: 0.25% @ Full Scale
- Range: +25% @ Full Scale to -25% @ Full Scale  
(Saturation in internal arithmetic will occur at greater negative non-linearities.)

As it applies to Tcg:

- Resolution: 0.3 ppm/ $(^\circ\text{C})^2$
- Range: +/- 38ppm/ $(^\circ\text{C})^2$

As it applies to Tco:

2 settings are possible. It is possible to scale the effect of SOT by 8. If Tc\_cfg[1] is set, then both Tco and SOT's contribution to Tco are multiplied by 8.

- Resolution at unity scaling: 1.51nV/V/ $(^\circ\text{C})^2$  (input referred)
- Range: +/- 0.192 $\mu\text{V}/\text{V}/(^\circ\text{C})^2$  (input referred)
- Resolution at 8x scaling: 12.1nV/V/ $(^\circ\text{C})^2$  (input referred)
- Range: +/- 1.54 $\mu\text{V}/\text{V}/(^\circ\text{C})^2$  (input referred)

## 3.7. Reading EEPROM Contents

The contents of the entire EEPROM memory can be read out using the Read EEPROM command (00<sub>H</sub>). This command causes the IC to output consecutive bytes on the ZACwire™. After each transmission, the EEPROM contents are shifted by 8 bits. The bit order of these bytes is given in Table 3.11.

**Table 3.11 EEPROM Read Order**

	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Byte 1	Offset_B[7:0]							
Byte 2	Gain_T[1:0]		Offset_B[13:8]					
Byte 3	Offset_T[1:0]		Gain_T[7:2]					
Byte 4	T <sub>SETL</sub> [1:0]		Offset_T[7:2]					
Byte 5	T <sub>cg</sub> [2:0]			T <sub>SETL</sub> [6:2]				
Byte 6	T <sub>co</sub> [2:0]			T <sub>cg</sub> [7:3]				
Byte 7	T <sub>c_cfg</sub> [2:0]			T <sub>co</sub> [7:3]				
Byte 8	SOT[7:0]							
Byte 9	Lock[0]	Diag_cfg[2:0]			SOT_cfg[3:0]			
Byte 10	Up_Clip_Lim[5:0]					Lock[2:1]		
Byte 11	Low_Clip_Lim[6:0]						Up_Clip_Lim[6]	
Byte 12	Cust_ID0[7:0]							
Byte 13	Cust_ID1[7:0]							
Byte 14	Cust_ID2[7:0]							
Byte 15	Signature[7:0]							
Byte 16	A2D_Offset[0]	1V_Trim[3:0] **				Osc_Trim[2:0] **		
Byte 17	JFET_cfg[0]	Update_Rate[1:0]		Output Select[1:0]		A2D_Offset[3:1]		
Byte 18	Gain_B[6:0]						JFET_cfg[1]	
Byte 19	Gain_B[14:7]							
Byte 20	A5 <sub>H</sub>							
* SOT_cfg/Pamp_Gain								
** 1V_Trim/JFET_Trim								

## 4 Application Circuit Examples

The minimum output analog load resistor is  $R_L = 5k\Omega$ . This optional load resistor can be configured as a pull-up or pull-down. If it is configured as a pull-down, it cannot be part of the module to be calibrated because this would prevent proper operation of the ZACwire<sup>TM</sup>. If a pull-down load is desired, it must be added to system after module calibration.

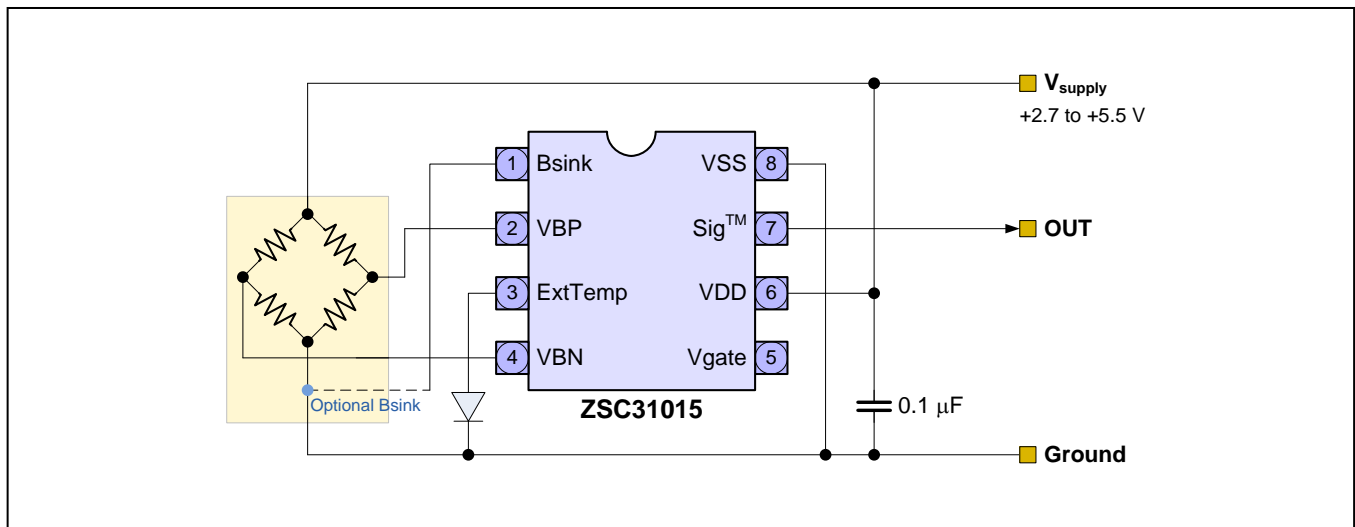

There is no output load capacitance needed.

EEPROM contents: OUTPUT\_select, Config\_JFET\_Regulation, 1V\_Trim/JFET-Trim.

### 4.1. Three-Wire Rail-to-Rail Ratiometric Output

This example shows an application circuit for rail-to-rail ratiometric voltage output configuration with temperature compensation via an external diode. The same circuitry is applicable for a 0 to 1V absolute analog output.

**Figure 4.1 Rail-to-Rail Ratiometric Voltage Output – Temperature Compensation via External Diode**

The optional bridge sink allows a power savings of bridge current. The output voltage can be either

- Rail-to-rail ratiometric analog output  $V_{DD}(=V_{supply})$ .
- 0 to 1V absolute analog output. The absolute voltage output reference is trimmable 1V (+/-3mV) in the 1V Output Mode via a 4-bit EEPROM field. See section 2.4.3).

## 4.2. Absolute Analog Voltage Output

The figure below shows an application circuit for an absolute voltage output configuration with temperature compensation via internal temperature PTAT and external JFET regulation for all industry standard applications.

**Figure 4.2 Absolute Analog Voltage Output – Temperature Compensation via Internal Temperature PTAT with External JFET Regulation**

The output signal range can be one of the following options:

- 0 to 1 V analog output. The absolute voltage output reference is trimmable: 1 V (+/-3 mV) in the 1 V Output Mode via a 4-bit EEPROM field (see section 2.4.3).
- Rail-to-rail analog output. The on-chip reference for the JFET regulator block is trimmable: 5 V (±15 mV) in the Ratiometric Output Mode via a 4-bit EEPROM field. (See section 2.4.3).

## 4.3. Three-Wire Ratiometric Output with Over-Voltage Protection

The figure below shows an application circuit for a ratiometric output configuration with temperature compensation via an internal diode. In this application, the JFET is used for voltage protection. JFET\_cfg (16:15) in the EEPROM are configured to 5.5V. There is an additional maximum error of 8mV caused by the non-zero  $r_{ON}$  of the limiter JFET.

**Figure 4.3 Ratiometric Output, Temperature Compensation via Internal Diode**

## 4.4. Digital Output

For all three circuits, the output signal can also be digital. Depending on the output select bits, the bridge signal or the bridge signal and temperature signal are sent. For the digital output, no load resistor or load capacity is necessary. No pull down resistor is allowed. If a line resistor or pull-up resistor is used, the requirement for the rise time must be met ( $< 5 \mu\text{s}$ ). The IC output includes an internal pull up resistor of about 30 k $\Omega$ . The digital output can easily be read by firmware from a microcontroller, and ZMDI can provide the customer with software for developing the interface.

## 4.5. Output Resistor/Capacitor Limits

The limits for external components depend on the programmed output mode:

- Pure Analog Output Mode (calibration is done before): The only limit is the minimum load resistance of 5 k $\Omega$ .
- Pure Digital Output Mode with end-of-line calibration: The RC time constant of the ZACwire™ line must have a rise time  $< 5 \mu\text{s}$ .
- Analog output with digital communication during calibration: The RC time constant of the ZACwire™ line must have a rise time  $< 5 \mu\text{s}$ .

**Warning:** Any series line resistance forms a voltage divider in conjunction with the pull-up load device. If a series line resistance is needed, choose a low value relative to the pull-up load device.

## 5 EEPROM Restoration

If needed, the default settings for the ZSC31015 (see Table 3.5) can be reprogrammed as described in section 3. The following sections describe EEPROM content validation and handling during and/or after system assembly.

**Important:** During the sawing and dicing process, there is a possibility of the EEPROM contents flipping, and prevention cannot be guaranteed. This is primarily a concern for the factory trim settings, which are customized to each part.

The EEPROM default values programmed during the different test levels have been selected so that customer has the option to refresh/reprogram trim bits that might have flipped during sawing or dicing.

**Important:** The EEPROM lock is stored in the bit range 105:103. A value of 0x6 or 0x3 will lock the EEPROM forever by disabling the charge pump needed for EEPROM writing. The complete contents can also be validated using the EEPROM signature stored in bits [151:144], (see “Signature” in Table 3.5).

### 5.1. Default EEPROM Contents

During the wafer level test (wafer/dice delivery) and during final test for SOP8 packaged parts, the EEPROM is programmed with the default values listed in the Table 3.5. During the wafer level test, the Osc\_trim bits [2:0] and 1V\_Trim/JFET\_Trim trim bits [6:3] are set to die-specific values.

#### 5.1.1. Osc\_Trim

The oscillator frequency is trimmed to a value of 512kHz±20% using the Osc\_Trim bit setting. The 3-bit setting is copied twice to Cust\_ID1[134:132] and [130:128] and then a third time to Cust\_ID2[138:136] to ensure the factory settings are retained so that the customer can reprogram these values in the Osc\_Trim bit if needed. Based on the most probable trimming, the default values for the Osc\_Trim bits are always set to 0x0 during factory testing to guarantee communication even if bits have flipped.

#### 5.1.2. 1V\_Trim/JFET\_Trim

The 5V reference for the JFET regulation is factory trimmed during the final test to 5V±15mV using the 1V\_Trim/JFET\_Trim bit setting. The 4-bit setting stored in EEPROM bits [6:3] is copied twice to the Cust\_ID0 bits [127:124] and [123:120] to ensure the factory settings are retained so that the customer can reprogram these values in the 1V\_Trim/JFET\_Trim bits if needed.

### 5.2. EEPROM Restoration Procedure

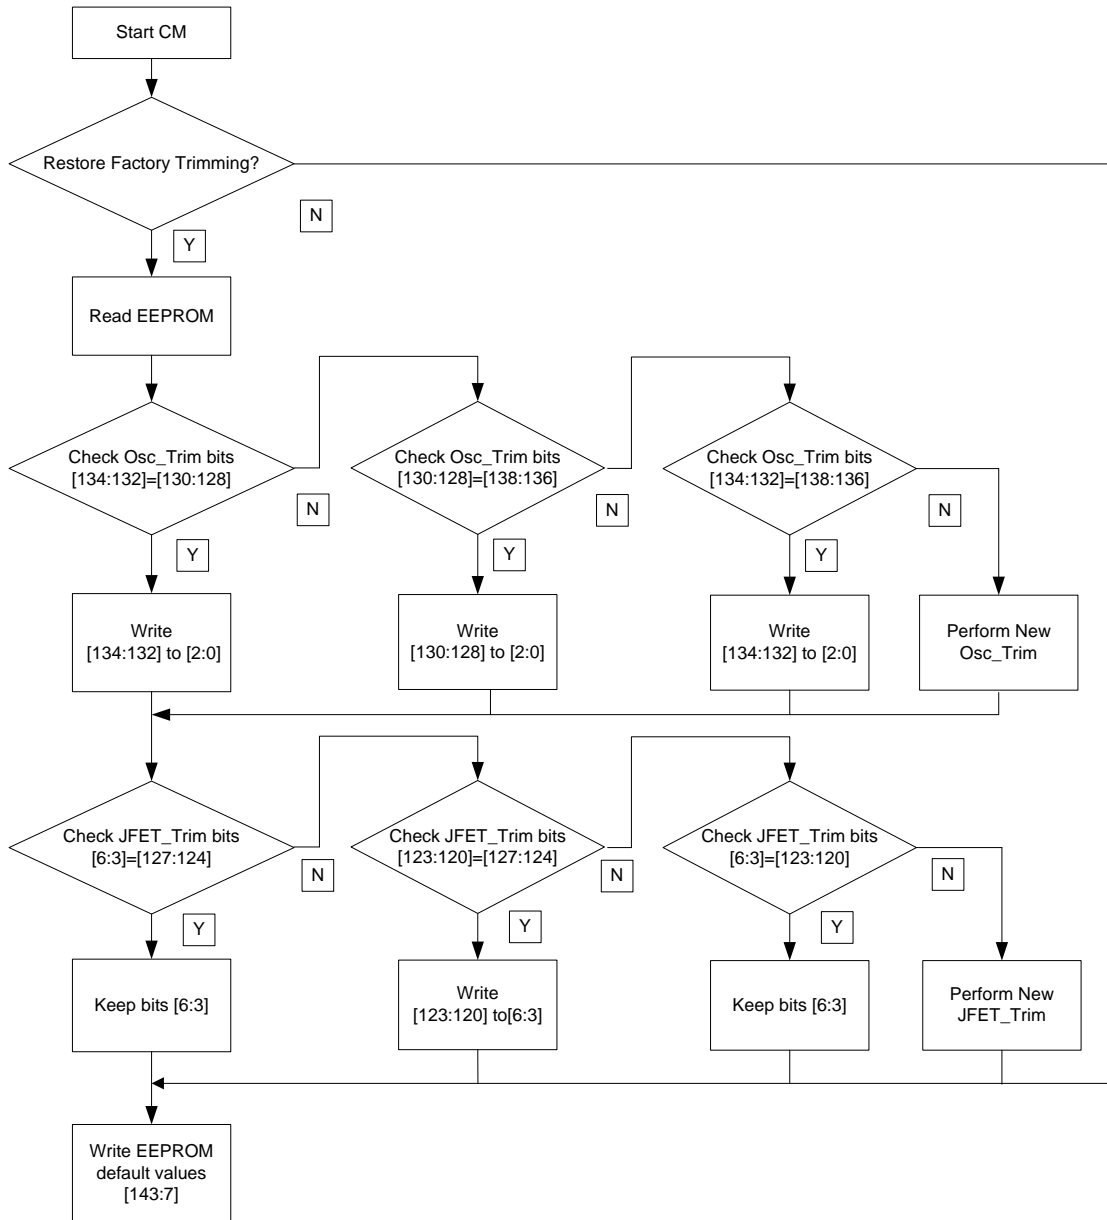

After module assembly, the EEPROM content should be refreshed. If JFET regulation is not used for the customer’s application and optimized response time is not an important criterion, write the default values shown in Table 3.5 to the EEPROM bit range [143:7] and retain the existing values in the bit range [6:0]. If JFET regulation or optimized response time is required, the bit restoration procedure shown in the flow chart in Figure 5.1 must be used to keep the factory settings programmed during the testing. If customer oscillator trimming is required, see *ZSC31015\_Tech\_Notes\_JFET\_and\_Osc\_Trimming\_revX.X.pdf* for instructions.)

Note: The EEPROM signature is re-calculated and updated after every EEPROM writing.

**Figure 5.1 EEPROM Validation and Restoration Procedure**

## 6 Pin Configuration and Package

The standard package of the RBic<sub>dLite</sub>™ is an SOP-8 (3.81 mm / 150 mil body) with a lead-pitch 1.27 mm / 50 mil.

**Table 6.1 Storage and Soldering Conditions for SOP-8 Package**

Parameter	Symbol	Conditions	Min	Typical	Max	Units
Maximum Storage Temperature	T <sub>max_storage</sub>	Less than 10hrs, before mounting			150	°C
Minimum Storage Temperature:	T <sub>min_storage</sub>	Store in original packing only	-50			°C
Maximum Dry-Bake Temperature	T <sub>drybake</sub>	Less than 100 hrs total, before mounting			125	°C
Soldering Peak Temperature	T <sub>peak</sub>	Less than 30s (IPC/JEDEC-STD-020 Standard)			260	°C

**Figure 6.1 ZSC31015 RBic<sub>dLite</sub>™ Pin-Out Diagram**

**Table 6.2 RBic<sub>dLite</sub>™ Pin Configuration**

Pin No.	Name	Description
1	Bsink	Optional ground connection for bridge ground. Used for power savings.
2	VBP	Positive bridge connection
3	ExtTemp	External diode connection
4	VBN	Negative bridge connection
5	Vgate	Gate control for external JFET regulation/over-voltage protection
6	VDD	Supply voltage (2.7 to 5.5 V)
7	Sig™	ZACwire™ interface (analog out, digital out, calibration interface)
8	VSS	Ground supply

The Analog Mixed Signal Company

## 7 ESD/Latch-Up-Protection

All pins have an ESD protection of >4000V and a latch-up protection of  $\pm 100$  mA or of +8V/ -4V (to VSS/VSSA). ESD protection referenced to the Human Body Model is tested with devices in SOP-8 packages during product qualification. The ESD test follows the Human Body Model with 1.5k $\Omega$ /100pF based on MIL 883, Method 3015.7.

## 8 Test

The test program is based on this datasheet. The final parameters which will be tested during series production are listed in the tables of section 1.

The digital part of the IC includes a scan path, which can be activated and controlled during wafer test. Further test support for testing of the analog parts on wafer level is included in the DSP.

## 9 Quality and Reliability

A reliability investigation according to the in-house non-automotive standard will be performed.

## 10 Customization

For high-volume applications, which require an upgraded or downgraded functionality compared to the ZSC31015, ZMDI can customize the circuit design by adding or removing certain functional blocks.

For this customization, ZMDI has a considerable library of sensor-dedicated circuitry blocks, which enable ZMDI to provide a custom solution quickly. Please contact ZMDI for further information.

## 14 Document Revision History

Revision	Date	Description
1.40	February 24, 2009	Revision to Byte 16 in Table 3.11. Revision to add an explanation for default setting in Table 3.5. Revision to “Lower Output Voltage Limit” specification in Table 1.7. Revisions in sections 2.4.3 and 2.5.1 to text regarding regulator set point and optimal reference trim, including text about methods for preserving factory settings. Revision to caption for Figure 3.2 to clarify that timing is typical. Revision to text below Table 3.2 regarding minimum and maximum baud rate. Added note below Table 3.3 clarifying that timing is typical. Revisions to the default settings column and explanations for the Cust_ID0 and Cust_ID1 EEPROM words in Table 3.5. Addition of section 5 to explain methods for restoration of EEPROM settings.
1.50	May 14, 2009	Revised conditions for “Overall Ratiometricity Error” and “Overall Accuracy – Analog” specifications (Table 1.11).
1.60	June 10, 2009	Added “Document Revision History” table.
1.70	March 29, 2010	Corrected start-up window time 1.5 to 3ms. This change applies only to rev C1 Silicon (marked as ZSC31015Cxx.) and higher. Stop bit definition is replaced by stop time definition. Relocated specs from Table 1.9 and deleted Table 1.9.
1.73	May 11, 2010	Added footnote to pages 2, 3, and 14 clarifying that the ZSC31015 is not AEC-Q100-qualified.
1.74	July 19, 2010	Added special measurement information to Table 3.2; revised precondition for equation (1).
1.80	July 27, 2010	Revised product name from ZMD31015 to ZSC31015.
1.90	March 24, 2011	Added EEPROM specifications to section 1.3 “Electrical Parameters.” Added table 6.1 “Storage and Soldering Conditions” to section 6 “Pin Configuration and Package.” Updated trim tolerances in sections 4.1 and 4.2. Updated ZMDI contact information.
1.91	October 8, 2011	Revisions in Table 1.6. Addition of part ordering numbers for all available temperature ranges to section 11. Update for sales contact information to add ZMDI’s Korea office. Revision of product title.
1.92	January 11, 2012	Removed requirement of fastest update rate for analog output mode (applied to previous IC revision). Updated contact information for the USA.
