**Register 12: QSSI Clock Configuration (SSICC), offset 0xFC8**

The **SSICC** register controls the baud clock source for the QSSI module.

**Note:** If ALTCLK is used for the QSSI baud clock, the system clock frequency must be at least twice that of the ALTCLK programmed value in Run mode.

**QSSI Clock Configuration (SSICC)**

## 21 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacturing. The TM4C129DNCZAD microcontroller includes providing the ability to communicate (both transmit and receive) with other I<sup>2</sup>C devices on the bus.

The TM4C129DNCZAD controller includes I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both transmitting and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Two 8-entry FIFOs for receive and transmit data
  - FIFOs can be independently assigned to master or slave
- Four transmission speeds:
  - Standard (100 Kbps)
  - Fast-mode (400 Kbps)
  - Fast-mode plus (1 Mbps)
  - High-speed mode (3.33 Mbps)
- Glitch suppression
- SMBus support through software
  - Clock low timeout interrupt
  - Dual slave address capability
  - Quick command capability
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)

- Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive
  - Ability to execute single data transfers or burst data transfers using the RX and TX FIFOs in the I<sup>2</sup>C

## 21.1 Block Diagram

Figure 21-1. I<sup>2</sup>C Block Diagram

## 21.2 Signal Description

The following table lists the external signals of the I<sup>2</sup>C interface and describes the function of each. The I<sup>2</sup>C interface signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the I<sup>2</sup>C signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to choose the I<sup>2</sup>C function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPTCL)** register (page 788) to assign the I<sup>2</sup>C signal to the specified GPIO port pin. Note that the I2CSDA pin should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 741.

## 21.3 Functional Description

Each I<sup>2</sup>C module is comprised of both master and slave functions and is identified by a unique address. A master-initiated communication generates the clock signal, SCL. For proper operation, the SDA pin must be configured as an open-drain signal. Due to the internal circuitry that supports high-speed operation, the SCL pin must not be configured as an open-drain signal, although the internal circuitry causes it to act as if it were an open drain signal. Both SDA and SCL signals must be connected to a positive supply voltage using a pull-up resistor. A typical I<sup>2</sup>C bus configuration is shown in Figure 21-2. Refer to the *I<sup>2</sup>C-bus specification and user manual* to determine the size of the pull-ups needed for proper operation.

See “Inter-Integrated Circuit (I<sup>2</sup>C) Interface” on page 1944 for I<sup>2</sup>C timing diagrams.

Figure 21-2. I<sup>2</sup>C Bus Configuration

### 21.3.1 I<sup>2</sup>C Bus Functional Overview

The I<sup>2</sup>C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on TM4C129DNCZAD microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the I<sup>2</sup>C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 1398) is unrestricted, but each data byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

### 21.3.1.1 START and STOP Conditions

The protocol of the I<sup>2</sup>C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 21-3.

**Figure 21-3. START and STOP Conditions**

The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due to an error), the interrupt pin becomes active and the data may be read from the **I<sup>2</sup>C Master Data (I2CMDR)** register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit is normally set causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

When operating in slave mode, the STARTRIS and STOPRIS bits in the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register indicate detection of start and stop conditions on the bus and the **I<sup>2</sup>C Slave Masked Interrupt Status (I2CSMIS)** register can be configured to allow STARTRIS and STOPRIS to be promoted to controller interrupts (when interrupts are enabled).

### 21.3.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 21-4. After the START condition, a slave address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (R/S bit in the **I2CMSA** register). If the R/S bit is clear, it indicates a transmit operation (send), and if it is set, it indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/transmit formats are then possible within a single transfer.

**Figure 21-4. Complete Data Transfer with a 7-Bit Address**

The first seven bits of the first byte make up the slave address (see Figure 21-5). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

**Figure 21-5. R/S Bit in First Byte**

### 21.3.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 21-6).

**Figure 21-6. Data Validity During Bit Transfer on the I<sup>2</sup>C Bus**

### 21.3.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data transmitted out by the receiver during the acknowledge cycle must comply with the data validity requirements described in “Data Validity” on page 1399.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Because the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

If the slave is required to provide a manual ACK or NACK, the **I<sup>2</sup>C Slave ACK Control (I2CSACKCTL)** register allows the slave to NACK for invalid data or command or ACK for valid data or command. When this operation is enabled, the MCU slave module I<sup>2</sup>C clock is pulled low after the last data bit until this register is written with the indicated response.

### 21.3.1.5 Repeated Start

The I<sup>2</sup>C master module has the capability of executing a repeated START (transmit or receive) after an initial transfer has occurred.

A repeated start sequence for a Master transmit is as follows:

1. When the device is in the idle state, the Master writes the slave address to the **I2CMSA** register and configures the R/S bit for the desired transfer type.
2. Data is written to the **I2CMDR** register.
3. When the BUSY bit in the **I2CMCS** register is 0, the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSA** register and then writes 0x3 to initiate the repeated START.

A repeated start sequence for a Master receive is similar:

1. When the device is in idle, the Master writes the slave address to the **I2CMSA** register and configures the R/S bit for the desired transfer type.
2. The master reads data from the **I2CMDR** register.
3. When the BUSY bit in the **I2CMCS** register is 0, the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSA** register and then writes 0x3 to initiate the repeated START.

For more information on repeated START, refer to Figure 21-12 on page 1413 and Figure 21-13 on page 1414.

### 21.3.1.6 Clock Low Timeout (CLTO)

The I<sup>2</sup>C slave can extend the transaction by pulling the clock low periodically to create a slow bit transfer rate. The I<sup>2</sup>C module has a 12-bit programmable counter that is used to track how long the clock has been held low. The upper 8 bits of the count value are software programmable through the **I<sup>2</sup>C Master Clock Low Timeout Count (I2CMCLKOCNT)** register. The lower four bits are not user visible and are 0x0. The CNTL value programmed in the **I2CMCLKOCNT** register has to be greater than 0x01. The application can program the eight most significant bits of the counter to reflect the acceptable cumulative low period in transaction. The count is loaded at the START condition and counts down on each falling edge of the internal bus clock of the Master. Note that the internal bus clock generated for this counter keeps running at the programmed I<sup>2</sup>C speed even if SCL is held low on the bus. Upon reaching terminal count, the master state machine forces ABORT on the bus by issuing a STOP condition at the instance of SCL and SDA release.

As an example, if an I<sup>2</sup>C module was operating at 100 kHz speed, programming the **I2CMCLKOCNT** register to 0xDA would translate to the value 0xDA0 since the lower four bits are set to 0x0. This would translate to a decimal value of 3488 clocks or a cumulative clock low period of 34.88 ms at 100 kHz.

The CLKRIS bit in the **I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS)** register is set when the clock timeout period is reached, allowing the master to start corrective action to resolve the remote slave state. In addition, the CLKTO bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register is set; this bit

is cleared when a STOP condition is sent or during the I<sup>2</sup>C master reset. The status of the raw SDA and SCL signals are readable by software through the SDA and SCL bits in the **I<sup>2</sup>C Master Bus Monitor (I2CMBMON)** register to help determine the state of the remote slave.

In the event of a CLTO condition, application software must choose how it intends to attempt bus recovery. Most applications may attempt to manually toggle the I<sup>2</sup>C pins to force the slave to let go of the clock signal (a common solution is to attempt to force a STOP on the bus). If a CLTO is detected before the end of a burst transfer, and the bus is successfully recovered by the master, the master hardware attempts to finish the pending burst operation. Depending on the state of the slave after bus recovery, the actual behavior on the bus varies. If the slave resumes in a state where it can acknowledge the master (essentially, where it was before the bus hang), it continues where it left off. However, if the slave resumes in a reset state (or if a forced STOP by the master causes the slave to enter the idle state), it may ignore the master's attempt to complete the burst operation and NAK the first data byte that the master sends or requests.

Since the behavior of slaves cannot always be predicted, it is suggested that the application software always write the STOP bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register during the CLTO interrupt service routine. This limits the amount of data the master attempts to send or receive upon bus recovery to a single byte, and after the single byte is on the wire, the master issues a STOP. An alternative solution is to have the application software reset the I<sup>2</sup>C peripheral before attempting to manually recover the bus. This solution allows the I<sup>2</sup>C master hardware to be returned to a known good (and idle) state before attempting to recover a stuck bus and prevents any unwanted data from appearing on the wire.

**Note:** The Master Clock Low Timeout counter counts for the entire time SCL is held Low continuously. If SCL is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the **I2CMCLKOCNT** register and begins counting down from this value.

### 21.3.1.7 Dual Address

The I<sup>2</sup>C interface supports dual address capability for the slave. The additional programmable address is provided and can be matched if enabled. In legacy mode with dual address disabled, the I<sup>2</sup>C slave provides an ACK on the bus if the address matches the OAR field in the **I2CSOAR** register. In dual address mode, the I<sup>2</sup>C slave provides an ACK on the bus if either the OAR field in the **I2CSOAR** register or the OAR2 field in the **I2CSOAR2** register is matched. The enable for dual address is programmable through the OAR2EN bit in the **I2CSOAR2** register and there is no disable on the legacy address.

The OAR2SEL bit in the **I2CSCSR** register indicates if the address that was ACKed is the alternate address or not. When this bit is clear, it indicates either legacy operation or no address match.

### 21.3.1.8 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a 1 (High) on SDA, while another master transmits a 0 (Low), switches off its data output stage and retires until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

If arbitration is lost when the I2C master is initiating a BURST with the TX FIFO enabled, the application should execute the following steps to correctly handle the arbitration loss:

1. Flush and disable the TX FIFO
2. Clear and mask the TXFE interrupt by clearing the TXFEIM bit in the **I2CMIMR** register.

Once the bus is IDLE, the TXFIFO can be filled and enabled, the TXFE bit can be unmasked and a new BURST transaction can be initiated.

### 21.3.1.9 Glitch Suppression in Multi-Master Configuration

When a multi-master configuration is being used, the PULSESEL bit in the **I2CMTPR** register can be programmed to provide glitch suppression on the SCL and SDA lines and assure proper signal values. The glitch suppression value is in terms of buffered system clocks. Note that all signals will be delayed internally when glitch suppression is nonzero. For example, if PULSESEL is set to 0x7, 31 clocks should be added onto the calculation for the expected transaction time.

### 21.3.1.10 SMBus Operation

The SMBus interface is based on the I<sup>2</sup>C protocol; however, some differences exist between the two. These differences must be handled through software in order to make sure the SMBus protocol, including timing specifications, is met. Note that the SMBus 2.0 specification limits the maximum frequency of the interface to 100 KHz, as a result, I<sup>2</sup>C Standard speed operation is used for SMBus.

The SMBus/ I<sup>2</sup>C slave can extend the transaction if it is not ready by pulling the clock low. The SMBus specification allows the maximum timeout for such elongated transaction to be between 25 to 35 ms. The I<sup>2</sup>C specification does not have this requirement. The I<sup>2</sup>C module supports a programmable count to support clock-low timeout for the master to error out and take appropriate action as required. This feature is explained in "Clock Low Timeout (CLTO)" on page 1400. Note that if transactions are extended, a timeout period should be programmed in the **I2CMCLKOCNT** register, and the CLKRIS bit in the **I2CMRIS** register should not be masked.

Unlike the I<sup>2</sup>C slave, the SMBus slave must respond with an ACK response to its address regardless of whether it is ready or not. As a result, the I<sup>2</sup>C slave sends an ACK response to its address and a NACK response on the data byte if it is not ready. The ARBLST bit in the **I2CMCS** register is set if there were any issues with the transfer. In addition, the slave can send a NACK at any time to force the master to stop sending additional bytes.

The I<sup>2</sup>C Interface supports  $\mu$ DMA for efficient data handling. The  $\mu$ DMA operation needs FIFOs to be enabled for appropriate transfer type to perform I<sup>2</sup>C Master for burst transfers and all types of Slave transfers. The I<sup>2</sup>C interface is supported by two channels, one for Rx (I<sup>2</sup>C to Memory) and one for Tx (Memory to I<sup>2</sup>C) transfers.. See "FIFO and  $\mu$ DMA Operation" on page 1406 for more information.

#### Quick Command

Quick Command is a simple, compact SMBus protocol that sends an address and 1-bit of data in the R/S bit of the I<sup>2</sup>C header byte to communicate a command to the slave, typically a "turn off" or "turn on". The I<sup>2</sup>C master peripheral has the ability to send a Quick Command by writing the target address and R/S value into the **I2CMSA** register followed by a write to **I2CMCS** with a value of 0x27. SMBus requires the slave to be able to accept and process commands and the master to generate the Quick Command transactions. The master also has the capability to stop the transaction after acknowledgement from a slave.

The I<sup>2</sup>C slave peripheral requires special handling when a Quick Command is sent. In the case where a master sends a Quick Command with the R/S (data) bit cleared, the QCMDST bit in **I2CSCSR** is set, and the QCMDRW bit shows the data value (which in this case is 0) when the STOPRIS bit is set in **I2CSRIS** and the STOP interrupt is asserted. In this scenario, a DATARIS interrupt bit is not

set. When the master sends a Quick Command with the R/S (data) bit set, the DATARIS bit is set to notify the slave to write a data byte to **I2CSDR** in which bit 7 is set. A “dummy write” of 0xFF to the **I2CSDR** register is recommended. After the write to **I2CSDR**, the STOP interrupt is asserted and the QCMDST and QCMDRW bits are set in the **I2CSCSR** register to indicate that a quick command read occurred and the last transaction was a Quick Command. Therefore, when the slave must receive a Quick Command, it should be expecting such a command because it must write the **I2CSDR** with a specific value when R/S is set.

### 21.3.2 Available Speed Modes

The I<sup>2</sup>C bus can run in Standard mode (100 kbps), Fast mode (400 kbps), Fast mode plus (1 Mbps) or High-Speed mode (3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines). The selected mode should match the speed of the other I<sup>2</sup>C devices on the bus.

#### 21.3.2.1 Standard, Fast, and Fast Plus Modes

Standard, Fast, and Fast Plus modes are selected using a value in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register that results in an SCL frequency of 100 kbps for Standard mode, 400 kbps for Fast mode, or 1 Mbps for Fast mode plus.

The I<sup>2</sup>C clock rate is determined by the parameters *CLK\_PRD*, *TIMER\_PRD*, *SCL\_LP*, and *SCL\_HP* where:

*CLK\_PRD* is the system clock period

*SCL\_LP* is the low phase of SCL (fixed at 6)

*SCL\_HP* is the high phase of SCL (fixed at 4)

*TIMER\_PRD* is the programmed value in the **I2CMTPR** register (see page 1432). This value is determined by replacing the known variables in the equation below and solving for *TIMER\_PRD*.

The I<sup>2</sup>C clock period is calculated as follows:

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD$$

For example:

$$CLK\_PRD = 50 \text{ ns}$$

$$TIMER\_PRD = 2$$

$$SCL\_LP = 6$$

$$SCL\_HP = 4$$

yields a SCL frequency of:

$$1/SCL\_PERIOD = 333 \text{ KHz}$$

Table 21-2 gives examples of the timer periods that should be used to generate Standard, Fast mode, and Fast mode plus SCL frequencies based on various system clock frequencies.

**Table 21-2. Examples of I<sup>2</sup>C Master Timer Period Versus Speed Mode**

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode | Timer Period | Fast Mode Plus |
|--------------|--------------|---------------|--------------|-----------|--------------|----------------|
| 4 MHz        | 0x01         | 100 Kbps      | -            | -         | -            | -              |
| 6 MHz        | 0x02         | 100 Kbps      | -            | -         | -            | -              |

Table 21-2. Examples of I<sup>2</sup>C Master Timer Period Versus Speed Mode (continued)

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode | Timer Period | Fast Mode Plus |
|--------------|--------------|---------------|--------------|-----------|--------------|----------------|
| 12.5 MHz     | 0x06         | 89 Kbps       | 0x01         | 312 Kbps  | -            | -              |
| 16.7 MHz     | 0x08         | 93 Kbps       | 0x02         | 278 Kbps  | -            | -              |
| 20 MHz       | 0x09         | 100 Kbps      | 0x02         | 333 Kbps  | -            | -              |
| 25 MHz       | 0x0C         | 96.2 Kbps     | 0x03         | 312 Kbps  | -            | -              |
| 33 MHz       | 0x10         | 97.1 Kbps     | 0x04         | 330 Kbps  | -            | -              |
| 40 MHz       | 0x13         | 100 Kbps      | 0x04         | 400 Kbps  | 0x01         | 1000 Kbps      |
| 50 MHz       | 0x18         | 100 Kbps      | 0x06         | 357 Kbps  | 0x02         | 833 Kbps       |
| 80 MHz       | 0x27         | 100 Kbps      | 0x09         | 400 Kbps  | 0x03         | 1000 Kbps      |
| 100 MHz      | 0x31         | 100 Kbps      | 0x0C         | 385 Kbps  | 0x04         | 1000 Kbps      |
| 120 MHz      | Pending      | Pending       | Pending      | Pending   | Pending      | Pending        |

### 21.3.2.2 High-Speed Mode

The TM4C129DNCZAD I<sup>2</sup>C peripheral has support for High-speed operation as both a master and slave. High-Speed mode is configured by setting the HS bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register. High-Speed mode transmits data at a high bit rate with a 66.6%/33.3% duty cycle, but communication and arbitration are done at Standard, Fast mode, or Fast-mode plus speed, depending on which is selected by the user. When the HS bit in the **I2CMCS** register is set, current mode pull-ups are enabled.

The clock period can be selected using the equation below, but in this case, SCL\_LP=2 and SCL\_HP=1.

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD$$

So for example:

CLK\_PRD = 25 ns

TIMER\_PRD = 1

SCL\_LP=2

SCL\_HP=1

yields a SCL frequency of:

$$1/T = 3.33 \text{ Mhz}$$

Table 21-3 on page 1404 gives examples of timer period and system clock in High-Speed mode. Note that the HS bit in the **I2CMTPR** register needs to be set for the TPR value to be used in High-Speed mode.

Table 21-3. Examples of I<sup>2</sup>C Master Timer Period in High-Speed Mode

| System Clock | Timer Period | Transmission Mode |
|--------------|--------------|-------------------|
| 40 MHz       | 0x01         | 3.33 Mbps         |
| 50 MHz       | 0x02         | 2.77 Mbps         |
| 80 MHz       | 0x03         | 3.33 Mbps         |

When operating as a master, the protocol is shown in Figure 21-7. The master is responsible for sending a master code byte in either Standard (100 Kbps) or Fast-mode (400 Kbps) before it begins

transferring in High-speed mode. The master code byte must contain data in the form of 0000.1XXX and is used to tell the slave devices to prepare for a High-speed transfer. The master code byte should never be acknowledged by a slave since it is only used to indicate that the upcoming data is going to be transferred at a higher data rate. To send the master code byte for a standard high-speed transfer, software should place the value of the master code byte into the **I2CMSA** register and write the **I2CMCS** register with a value of 0x13. If a high-speed burst transfer is required, then to send the master code byte, software should place the value of the master code byte into the **I2CMSA** register and write the **I2CMCS** register with 0x50. Either configuration places the I<sup>2</sup>C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the HS bit in the **I2CMCS** register. Again, setting the HS bit in the **I2CMCS** register is only necessary during the master code byte.

When operating as a High-speed slave, there is no additional software required.

**Figure 21-7. High-Speed Data Format**

**Note:** High-Speed mode is 3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines.

### 21.3.3 Interrupts

The I<sup>2</sup>C can generate interrupts when the following conditions are observed in the Master Module:

- Master transaction completed (RIS bit)
- Master arbitration lost (ARBL0STRIS bit)
- Master Address/Data NACK (NACKRIS bit)
- Master bus timeout (CLKRIS bit)
- Next byte request (RIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)

- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

Interrupts are generated when the following conditions are observed in the Slave Module:

- Slave transaction received (DATARIS bit)
- Slave transaction requested (DATARIS bit)
- Slave next byte transfer request (DATARIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Programmable trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Programmable trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)
- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

The I<sup>2</sup>C master and I<sup>2</sup>C slave modules have separate interrupt registers. Interrupts can be masked by clearing the appropriate bit in the **I<sup>2</sup>C MIMR** or **I<sup>2</sup>C SIMR** register. Note that the RIS bit in the **Master Raw Interrupt Status (I<sup>2</sup>CMRIS)** register and the DATARIS bit in the **Slave Raw Interrupt Status (I<sup>2</sup>CSRIS)** register have multiple interrupt causes including a next byte transfer request interrupt. This interrupt is generated when both master and slave are requesting a receive or transmit transaction.

#### **21.3.4 Loopback Operation**

The I<sup>2</sup>C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the LPBK bit in the **I<sup>2</sup>C Master Configuration (I<sup>2</sup>CMCR)** register. In loopback mode, the SDA and SCL signals from the master and are tied to the SDA and SCL signals of the slave module to allow internal testing of the device without having to go through I/O.

#### **21.3.5 FIFO and $\mu$ DMA Operation**

Both the master and the slave module have the capability to access two 8-byte FIFOs that can be used in conjunction with the  $\mu$ DMA for fast transfer of data. The transmit (TX) FIFO and receive (RX) FIFO can be independently assigned to either the I<sup>2</sup>C master or I<sup>2</sup>C slave. Thus, the following FIFO assignments are allowed:

- The transmit and receive FIFOs can be assigned to the master
- The transmit and receive FIFOs can be assigned to the slave

- The transmit FIFO can be assigned to the master, while the receive FIFO is assigned to the slave and vice versa.

In most cases, both FIFOs will be assigned to either the master or the slave. The FIFO assignment is configured by programming the TXASGNMT and RXASGNMT bit in the **I<sup>2</sup>C FIFO Control (I2CFIFOCTL)** register.

Each FIFO has a programmable threshold point which indicates when the FIFO service interrupt should be generated. Additionally, a FIFO receive full and transmit empty interrupt can be enabled in the Interrupt Mask (**I2CxIMR**) registers of both the master and slave. Note that if we clear the TXFERIS interrupt (by setting the TXFEIC bit) when the TX FIFO is empty, the TXFERIS interrupt does not reassert even though the TX FIFO remains empty in this situation.

When a FIFO is not assigned to a master or a slave module, the FIFO interrupt and status signals to the module are forced to a state that indicates the FIFO is empty. For example, if the TX FIFO is assigned to the master module, the status signals to the slave transmit interface indicates that the FIFO is empty.

**Note:** The FIFOs must be empty when reassigning the FIFOs for proper functionality

### 21.3.5.1 Master Module Burst Mode

A BURST command is provided for the master module which allows a sequence of data transfers using the  $\mu$ DMA (or software, if desired) to handle the data in the FIFO. The BURST command is enabled by setting the BURST bit in the **Master Control/Status (I2CMCS)** register. The number of bytes transferred by a BURST request is programmed in the **I2C Master Burst Length (I2CMBLEN)** register and a copy of this value is automatically written to the **I2C Master Burst Count (I2CMBCNT)** register to be used as a down-counter during the BURST transfer. The bytes written to the **I2C FIFO Data (I2CFIFODATA)** register are transferred to the RX FIFO or TX FIFO depending on whether a transmit or receive is being executed. If data is NACKed during a BURST and the STOP bit is set in the **I2CMCS** register, the transfer terminates. If the STOP bit is not set, the software application must issue a repeated STOP or START when a NACK interrupt is asserted. In the case of a NACK, the **I2CMBCNT** register can be used to determine the amount of data that was transferred prior to the BURST termination. If the Address is NACKed during a transfer, then a STOP is issued.

#### **Master Module $\mu$ DMA Functionality**

When the **Master Control/Status (I2CMCS)** register is set to enable BURST and the master I<sup>2</sup>C  $\mu$ DMA channel is enabled in the **DMA Channel Map Select n (DMACHMAPn)** registers in the  $\mu$ DMA, the master control module will assert either the internal single  $\mu$ DMA request signal (dma\_sreq) or multiple  $\mu$ DMA request signal (dma\_req) to the  $\mu$ DMA. Note that there are separate dma\_req and dma\_sreq signals for transmit and receive. A single  $\mu$ DMA request (dma\_sreq) will be asserted by the Master module when the Rx FIFO has at least one data byte present in the FIFO and/or when the Tx FIFO has at least one space available to fill. The dma\_req (or Burst) signal will be asserted when Rx FIFO fill level is higher than trigger level and/or the Tx FIFO burst length remaining is less than 4 bytes and the FIFO fill level is less than trigger level. If a single transfer or BURST operation has completed, the  $\mu$ DMA sends a dma\_done signal to the master module represented by the DMATX/DMARX interrupts in the **I2CMIMR/I2CMRIS/I2CMMIS/I2CMICR** registers.

If the  $\mu$ DMA I<sup>2</sup>C channel is disabled and software is used to handle the BURST command, software can read the **FIFO Status (I2CFIFOSTAT)** Register and the **Master Burst Count (I2CMBC)** register to determine whether the FIFO needs servicing during the BURST transaction. A trigger value can be programmed in the **I2CFIFOCTL** register to allow for interrupts at various fill levels of the FIFOs.

The NACK and ARBLOST bits in the interrupt status registers can be enabled to indicate no acknowledgement of data transfer or an arbitration loss on the bus.

When the Master module is transmitting FIFO data, software can fill the Tx FIFO in advance of setting the BURST bit in the **I2CMCS** register. If the FIFO is empty when the  $\mu$ DMA is enabled for BURST mode, the `dma_req` and `dma_sreq` both assert (assuming the **I2CMLEN** register is programmed to at least 4 bytes and the Tx FIFO fill level is less than the trigger set). If the **I2CMLEN** register value is less than 4 and the Tx FIFO is not full but more than trigger level, only `dma_sreq` will assert. Single requests will be generated as required to keep the FIFO full until the number of bytes specified in the **I2CMLEN** register has been transferred to the FIFO (and the **I2CMBCOUNT** register reaches 0x0). At this point, no further requests are generated until the next BURST command is issued. If the  $\mu$ DMA is disabled, FIFOs will be serviced based on the interrupts active in the Master interrupt status registers, the FIFO trigger values shown in the **I2CFIFOSTATUS** register and completion of a BURST transfer.

When the Master module is receiving FIFO data, the Rx FIFO is initially empty and no requests are asserted. If data is read from the slave and placed into the Rx FIFO, the `dma_sreq` signal to the  $\mu$ DMA is asserted to indicate there is data to be transferred. If the Rx FIFO contains at least 4 bytes, the `dma_req` signal is also asserted. The  $\mu$ DMA will continue to transfer data out of the Rx FIFO until it has reached the amount of bytes programmed in the **I2CMLEN** register.

**Note:** The TXFEIM interrupt mask bit in the **I2CMIMR** register should be clear (masking the TXFE interrupt) when the master is performing an RX Burst from the RXFIFO and should be unmasked before starting a TX FIFO transfers.

#### 21.3.5.2 Slave Module

The slave module also has the capability to use the  $\mu$ DMA in Rx and Tx FIFO data transfers. If the Tx FIFO is assigned to the slave module and the TXFIFO bit is set in the **I2CSCSR** register, the slave module will generate a single  $\mu$ DMA request, `dma_sreq`, if the master module requests the next byte transfer. If the FIFO fill level is less than the trigger level, a  $\mu$ DMA multiple transfer request, `dma_req`, will be asserted to continue data transfers from the  $\mu$ DMA.

If the Rx FIFO is assigned to the slave module and the RXFIFO bit is set in the **I2CSCSR** register, then the slave module will generate a signal  $\mu$ DMA request, `dma_sreq`, if there is any data to be transferred. The `dma_req` signal will be asserted when the Rx FIFO has more data than the trigger level programmed by the RXTRIG bit in the **I2CFIFOCTL** register.

**Note:** Best practice recommends that an application should not switch between the **I2CSDR** register and TX FIFO or vice versa for successive transactions.

### 21.3.6 Command Sequence Flow Charts

This section details the steps required to perform the various I<sup>2</sup>C transfer types in both master and slave mode. Refer to Table 21-5 on page 1427 for further sequence information.

#### 21.3.6.1 I<sup>2</sup>C Master Command Sequences

The figures that follow show the command sequences available for the I<sup>2</sup>C master.

Figure 21-8. Master Single TRANSMIT

Figure 21-9. Master Single RECEIVE

Figure 21-10. Master TRANSMIT of Multiple Data Bytes

Figure 21-11. Master RECEIVE of Multiple Data Bytes

**Figure 21-12. Master RECEIVE with Repeated START after Master TRANSMIT**

**Figure 21-13. Master TRANSMIT with Repeated START after Master RECEIVE**

Figure 21-14. Standard High Speed Mode Master Transmit

### 21.3.6.2 I<sup>2</sup>C Slave Command Sequences

Figure 21-15 on page 1416 presents the command sequence available for the I<sup>2</sup>C slave.

**Figure 21-15. Slave Command Sequence**

## 21.4 Initialization and Configuration

### 21.4.1 Configure the I<sup>2</sup>C Module to Transmit a Single Byte as a Master

The following example shows how to configure the I<sup>2</sup>C module to transmit a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I<sup>2</sup>C clock using the **RCGCI2C** register in the System Control module (see page 395).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 386). To find out which GPIO port to enable, refer to Table 29-5 on page 1887.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register (see page 771). To determine which GPIOs to configure, see Table 29-4 on page 1873.

4. Enable the I2CSDA pin for open-drain operation. See page 776.
5. Configure the PMCN fields in the **GPIOPCTL** register to assign the I<sup>2</sup>C signals to the appropriate pins. See page 788 and Table 29-5 on page 1887.
6. Initialize the I<sup>2</sup>C Master by writing the **I2CMCR** register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 100 Kbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

$$\begin{aligned} \text{TPR} &= (\text{System Clock} / (2 * (\text{SCL\_LP} + \text{SCL\_HP}) * \text{SCL\_CLK})) - 1; \\ \text{TPR} &= (20\text{MHz} / (2 * (6+4) * 100000)) - 1; \\ \text{TPR} &= 9 \end{aligned}$$

Write the **I2CMTPR** register with the value of 0x0000.0009.

8. Specify the slave address of the master and that the next operation is a Transmit by writing the **I2CMSA** register with a value of 0x0000.0076. This sets the slave address to 0x3B.
9. Place data (byte) to be transmitted in the data register by writing the **I2CMDR** register with the desired data.
10. Initiate a single byte transmit of the data from Master to Slave by writing the **I2CMCS** register with a value of 0x0000.0007 (STOP, START, RUN).
11. Wait until the transmission completes by polling the **I2CMCS** register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the **I2CMCS** register to confirm the transmit was acknowledged.

## 21.4.2 Configure the I<sup>2</sup>C Master to High Speed Mode

To configure the I<sup>2</sup>C master to High Speed mode:

1. Enable the I<sup>2</sup>C clock using the **RCGCI2C** register in the System Control module (see page 395).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 386). To find out which GPIO port to enable, refer to Table 29-5 on page 1887.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFASEL** register (see page 771). To determine which GPIOs to configure, see Table 29-4 on page 1873.
4. Enable the I2CSDA pin for open-drain operation. See page 776.
5. Configure the PMCN fields in the **GPIOPCTL** register to assign the I<sup>2</sup>C signals to the appropriate pins. See page 788 and Table 29-5 on page 1887.
6. Initialize the I<sup>2</sup>C Master by writing the **I2CMCR** register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 3.33 Mbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```
TPR = (System Clock / (2 * (SCL_LP + SCL_HP) * SCL_CLK)) - 1;  
TPR = (80 MHz / (2 * (2 + 1) * 3330000)) - 1;  
TPR = 3
```

Write the **I2CMTPR** register with the value of 0x0000.0003.

8. To send the master code byte, software should place the value of the master code byte into the I2CMSA register and write the I2CMCS register with the following value depending on the required operation:
  - For Standard High-Speed mode, the **I2CMCS** register should be written with 0x13.
  - For Burst High-Speed mode, the **I2CMCS** register should be written with 0x50.
9. This places the I2C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the HS bit in the **I2CMCS** register.
10. The transaction is ended by setting the STOP bit in the **I2CMCS** register.
11. Wait until the transmission completes by polling the **I2CMCS** register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the **I2CMCS** register to confirm the transmit was acknowledged.

## 21.5 Register Map

Table 21-4 on page 1419 lists the I<sup>2</sup>C registers. All addresses given are relative to the I<sup>2</sup>C base address:

- I<sup>2</sup>C 0: 0x4002.0000
- I<sup>2</sup>C 1: 0x4002.1000
- I<sup>2</sup>C 2: 0x4002.2000
- I<sup>2</sup>C 3: 0x4002.3000
- I<sup>2</sup>C 4: 0x400C.0000
- I<sup>2</sup>C 5: 0x400C.1000
- I<sup>2</sup>C 6: 0x400C.2000
- I<sup>2</sup>C 7: 0x400C.3000
- I<sup>2</sup>C 8: 0x400B.8000
- I<sup>2</sup>C 9: 0x400B.9000

Note that the I<sup>2</sup>C module clock must be enabled before the registers can be programmed (see page 395). There must be a delay of 3 system clocks after the I<sup>2</sup>C module clock is enabled before any I<sup>2</sup>C module registers are accessed.

The hw\_i2c.h file in the TivaWare™ Driver Library uses a base address of 0x800 for the I<sup>2</sup>C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that TivaWare™ for C Series uses an offset between 0x000 and 0x018 with the slave base address.

**Table 21-4. Inter-Integrated Circuit (I<sup>2</sup>C) Interface Register Map**

| Offset                                   | Name          | Type | Reset       | Description                        | See page |

## **21.6 Register Descriptions (I<sup>2</sup>C Master)**

The remainder of this section lists and describes the I<sup>2</sup>C master registers, in numerical order by address offset.

## Register 1: I<sup>2</sup>C Master Slave Address (I2CMSA), offset 0x000

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Transmit (Low).

### I2C Master Slave Address (I2CMSA)

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000  
 I2C 2 base: 0x4002.2000  
 I2C 3 base: 0x4002.3000  
 I2C 4 base: 0x400C.0000  
 I2C 5 base: 0x400C.1000  
 I2C 6 base: 0x400C.2000  
 I2C 7 base: 0x400C.3000  
 I2C 8 base: 0x400B.8000  
 I2C 9 base: 0x400B.9000  
 Offset 0x000  
 Type RW, reset 0x0000.0000

## Register 2: I<sup>2</sup>C Master Control/Status (I2CMCS), offset 0x004

This register accesses status bits when read and control bits when written. When read, the status register indicates the state of the I<sup>2</sup>C bus controller. When written, the control register configures the I<sup>2</sup>C controller operation.

The START bit generates the START or REPEATED START condition. The STOP bit determines if the cycle stops at the end of the data cycle or continues to the next transfer cycle, which could be a repeated START. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and this register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due an error), an interrupt becomes active and the data may be read from the **I2CMDR** register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit is normally set, causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

|   |       |    |   |       |
|---|-------|----|---|-------|
| 1 | ERROR | RO | 0 | Error |
|---|-------|----|---|-------|

Value Description

0 No error was detected on the last operation.

1 An error occurred on the last operation.

The error can be from the slave address not being acknowledged or the transmit data not being acknowledged.

|   |      |    |   |                       |
|---|------|----|---|-----------------------|
| 0 | BUSY | RO | 0 | I <sup>2</sup> C Busy |
|---|------|----|---|-----------------------|

Value Description

0 The controller is idle.

1 The controller is busy.

When the BUSY bit is set, the other status bits are not valid.

a. An X in a table cell indicates the bit can be 0 or 1.

- b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

### Register 3: I<sup>2</sup>C Master Data (I2CMDR), offset 0x008

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Master Transmit state and the data received when in the Master Receive state. If the BURST bit is enabled in the **I2CMCS** register, then the **I2CFIFODATA** register is used for the current data transmit or receive value and this register is ignored.

## Register 10: I<sup>2</sup>C Master Clock Low Timeout Count (I2CMCLKOCNT), offset 0x024

This register contains the upper 8 bits of a 12-bit counter that can be used to keep the timeout limit for clock stretching by a remote slave. The lower four bits of the counter are not user visible and are always 0x0.

**Note:** The Master Clock Low Timeout counter counts for the entire time SCL is held Low continuously. If SCL is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the **I2CMCLKOCNT** register and begins counting down from this value.

### Register 13: I<sup>2</sup>C Master Burst Count (I2CMBCNT), offset 0x034

When BURST is active, the value in the **I2CMLEN** register is copied into this register and decremented during the BURST transaction. This register can be used to determine the number of transfers that occurred when a BURST terminates early (as a result of a data NACK). When a BURST completes successfully, this register will contain 0.

## 21.7 Register Descriptions (I<sup>2</sup>C Slave)

The remainder of this section lists and describes the I<sup>2</sup>C slave registers, in numerical order by address offset.

**Register 14: I<sup>2</sup>C Slave Own Address (I2CSOAR), offset 0x800**

This register consists of seven address bits that identify the TM4C129DNCZAD I<sup>2</sup>C device on the I<sup>2</sup>C bus.

**I2C Slave Own Address (I2CSOAR)**

**Register 16: I<sup>2</sup>C Slave Data (I2CSDR), offset 0x808**

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Slave Transmit state, and the data received when in the Slave Receive state. If the RXFIFO bit or TXFIFO bit are enabled in the **I2CSCSR** register, then this register is ignored and the data value being transferred from the FIFO is contained in the **I2CFIFODATA** register.

**Note:** Best practice recommends that an application should not switch between the **I2CSDR** register and TX FIFO or vice versa for successive transactions.

**21.8 Register Descriptions (I<sup>2</sup>C Status and Control)**

The remainder of this section lists and describes the I<sup>2</sup>C status and control registers, in numerical order by address offset.

**Register 23: I<sup>2</sup>C FIFO Data (I2CFIFODATA), offset 0xF00**

The I<sup>2</sup>C FIFO Data (I2CFIFODATA) register contains the current value of the top of the RX or TX FIFO stack being used in the a transfer.

**Read-Only Status Register****I2C FIFO Data (I2CFIFODATA)**

I2C 0 base: 0x4002.0000

**Register 24: I<sup>2</sup>C FIFO Control (I2CFIFOCTL), offset 0xF04**

The FIFO Control Register can be programmed to control various aspects of the FIFO transaction, such as RX and TX FIFO assignment, byte count value for FIFO triggers and flushing of the FIFOs.

**I2C FIFO Control (I2CFIFOCTL)**

## 22 Controller Area Network (CAN) Module

Controller Area Network (CAN) is a multicast, shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically-noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths less than 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 meters).

The TM4C129DNCZAD microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CANnTX and CANnRX signals

## 22.1 Block Diagram

Figure 22-1. CAN Controller Block Diagram

## 22.2 Signal Description

The following table lists the external signals of the CAN controller and describes the function of each. The CAN controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the CAN signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to choose the CAN controller function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 788) to assign the CAN signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 741.

**Table 22-1. Controller Area Network Signals (212BGA)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description            |
|----------|------------|--------------------------|----------|-------------|------------------------|
| CAN0Rx   | V3<br>W10  | PA0 (7)<br>PT0 (7)       | I        | TTL         | CAN module 0 receive.  |
| CAN0Tx   | W3<br>V10  | PA1 (7)<br>PT1 (7)       | O        | TTL         | CAN module 0 transmit. |
| CAN1Rx   | A16<br>E18 | PB0 (7)<br>PT2 (7)       | I        | TTL         | CAN module 1 receive.  |
| CAN1Tx   | B16<br>F17 | PB1 (7)<br>PT3 (7)       | O        | TTL         | CAN module 1 transmit. |

## 22.3 Functional Description

The TM4C129DNCZAD CAN controller conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

A data frame contains data for transmission, whereas a remote frame contains no data and is used to request the transmission of a specific message object. The CAN data/remote frame is constructed as shown in Figure 22-2.

**Figure 22-2. CAN Data/Remote Frame**

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These memory blocks are accessed via either of the CAN message object register interfaces.

The message memory is not directly accessible in the TM4C129DNCZAD memory map, so the TM4C129DNCZAD CAN controller provides an interface to communicate with the message memory via two CAN interface register sets for communicating with the message objects. These two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that must be processed. In general, one interface is used for transmit data and one for receive data.

### 22.3.1 Initialization

To use the CAN controller, the peripheral clock must be enabled using the **RCGC0** register (see page 398). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register (see page 398). To find out which GPIO port to enable, refer to Table 29-4 on page 1873. Set the GPIO AFSEL bits for the appropriate pins (see page 771). Configure the PMCN fields in the **GPIOCTL** register to assign the CAN signals to the appropriate pins. See page 788 and Table 29-5 on page 1887.

Software initialization is started by setting the INIT bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While INIT is set, all message transfers to and from the CAN bus are stopped and the CANnTX signal is held High. Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible while in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, label it as not valid by clearing the MSGVAL bit in the **CAN IFn Arbitration 2 (CANIFnARB2)** register. Otherwise, the whole message object must be initialized, as the fields of the message object may not have valid information, causing unexpected results. Both the INIT and CCE bits in the **CANCTL** register must be set in order to access the **CANBIT** register and the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing. To leave the initialization state, the INIT bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (indicating a bus idle condition) before it takes part in bus activities and starts message transfers. Message object initialization does not require the CAN to be in the initialization state and can be done on the fly. However, message objects should all be configured to particular identifiers or set to not valid before message transfer starts. To change the configuration of a message object during normal operation, clear the MSGVAL bit in the **CANIFnARB2** register to indicate that the message object is not valid during the change. When the configuration is completed, set the MSGVAL bit again to indicate that the message object is once again valid.

### 22.3.2 Operation

Two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**) are used to access the message objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The two sets are independent and identical and can be used to

queue transactions. Generally, one interface is used to transmit data and one is used to receive data.

Once the CAN module is initialized and the INIT bit in the **CANCTL** register is cleared, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As each message is received, it goes through the message handler's filtering process, and if it passes through the filter, is stored in the message object specified by the MNUM bit in the **CAN IFn Command Request (CANIFnCRQ)** register. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the MSK bits in the **CAN IFn Mask 1** and **CAN IFn Mask 2 (CANIFnMSKn)** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers. The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. Message objects can be used for one-time data transfers or can be permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. At the start of transmission, the appropriate TXRQST bit in the **CAN Transmission Request n (CANTXRQn)** register and the NEWDAT bit in the **CAN New Data n (CANNWDAn)** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier (MNUM) for the message object, with 1 being the highest priority and 32 being the lowest priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

Transmission can be automatically started by the reception of a matching remote frame. To enable this mode, set the RMTEN bit in the **CAN IFn Message Control (CANIFnMCTL)** register. A matching received remote frame causes the TXRQST bit to be set, and the message object automatically transfers its data or generates an interrupt indicating a remote frame was requested. A remote frame can be strictly a single message identifier, or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The UMASK bit in the **CANIFnMCTL** register enables the MSK bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The MXTD bit in the **CANIFnMSK2** register should be set if a remote frame request is expected to be triggered by 29-bit extended identifiers.

### 22.3.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if a data transfer is not occurring between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's NEWDAT bit in the **CANNWDAn** register is cleared. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the TXRQST bit in the **CANTXRQn** register is cleared. If the CAN controller is configured to interrupt on a successful transmission of a message object, (the TXIE bit in the **CAN IFn Message Control (CANIFnMCTL)** register is set), the INTPND bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is

re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

### 22.3.4 Configuring a Transmit Message Object

The following steps illustrate how to configure a transmit message object.

1. In the **CAN IFn Command Mask (CANIFnCMASK)** register:
  - Set the WRNRD bit to specify a write to the **CANIFnCMASK** register; specify whether to transfer the IDMASK, DIR, and MXTD of the message object into the **CAN IFn** registers using the MASK bit
  - Specify whether to transfer the ID, DIR, XTD, and MSGVAL of the message object into the interface registers using the ARB bit
  - Specify whether to transfer the control bits into the interface registers using the CONTROL bit
  - Specify whether to clear the INTPND bit in the **CANIFnMCTL** register using the CLRINTPND bit
  - Specify whether to clear the NEWDAT bit in the **CANNWDAn** register using the NEWDAT bit
  - Specify which bits to transfer using the DATAA and DATAB bits
2. In the **CANIFnMSK1** register, use the MSK[15:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[15:0] in this register are used for bits [15:0] of the 29-bit message identifier and are not used for an 11-bit identifier. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. For a 29-bit identifier, configure ID[15:0] in the **CANIFnARB1** register for bits [15:0] of the message identifier and ID[12:0] in the **CANIFnARB2** register for bits [28:16] of the message identifier. Set the XTD bit to indicate an extended identifier; set the DIR bit to indicate transmit; and set the MSGVAL bit to indicate that the message object is valid.
5. For an 11-bit identifier, disregard the **CANIFnARB1** register and configure ID[12:2] in the **CANIFnARB2** register for bits [10:0] of the message identifier. Clear the XTD bit to indicate a standard identifier; set the DIR bit to indicate transmit; and set the MSGVAL bit to indicate that the message object is valid.
6. In the **CANIFnMCTL** register:

- Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the TXIE bit to enable the INTPND bit to be set after a successful transmission
  - Optionally set the RMTEN bit to enable the TXRQST bit to be set on the reception of a matching remote frame allowing automatic transmission
  - Set the EOB bit for a single message object
  - Configure the DLC[3:0] field to specify the size of the data frame. Take care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
7. Load the data to be transmitted into the **CAN IFn Data (CANIFnDA1, CANIFnDA2, CANIFnDB1, CANIFnDB2)** registers. Byte 0 of the CAN data frame is stored in DATA[7:0] in the **CANIFnDA1** register.
  8. Program the number of the message object to be transmitted in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register.
  9. When everything is properly configured, set the TXRQST bit in the **CANIFnMCTL** register. Once this bit is set, the message object is available to be transmitted, depending on priority and bus availability. Note that setting the RMTEN bit in the **CANIFnMCTL** register can also start message transmission if a matching remote frame has been received.

### 22.3.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the MSGVAL bit in the **CANIFnARB2** register nor the TXRQST bits in the **CANIFnMCTL** register have to be cleared before the update.

Even if only some of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn/CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU must write all four bytes into the **CANIFnDAn/CANIFnDBn** register or the message object is transferred to the **CANIFnDAn/CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the WRNRD, DATAA and DATAB bits in the **CANIFnMSKn** register are set, followed by writing the updated data into **CANIFnDA1, CANIFnDA2, CANIFnDB1, and CANIFnDB2** registers, and then the number of the message object is written to the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. To begin transmission of the new data as soon as possible, set the TXRQST bit in the **CANIFnMSKn** register.

To prevent the clearing of the TXRQST bit in the **CANIFnMCTL** register at the end of a transmission that may already be in progress while the data is updated, the NEWDAT and TXRQST bits have to be set at the same time in the **CANIFnMCTL** register. When these bits are set at the same time, NEWDAT is cleared as soon as the new transmission has started.

### 22.3.6 Accepting Received Message Objects

When the arbitration and control field (the ID and XTD bits in the **CANIFnARB2** and the RMTEN and DLC[3:0] bits of the **CANIFnMCTL** register) of an incoming message is completely shifted into the CAN controller, the message handling capability of the controller starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the controller uses the acceptance filtering programmed through the mask bits in the **CANIFnMSKn** register and enabled using the UMASK bit in the **CANIFnMCTL** register. Each valid

message object, starting with object 1, is compared with the incoming message to locate a matching message object in the message RAM. If a match occurs, the scanning is stopped and the message handler proceeds depending on whether it is a data frame or remote frame that was received.

### 22.3.7 Receiving a Data Frame

The message handler stores the message from the CAN controller receive shift register into the matching message object in the message RAM. The data bytes, all arbitration bits, and the DLC bits are all stored into the corresponding message object. In this manner, the data bytes are connected with the identifier even if arbitration masks are used. The NEWDAT bit of the **CANIFnMCTL** register is set to indicate that new data has been received. The CPU should clear this bit when it reads the message object to indicate to the controller that the message has been received, and the buffer is free to receive more messages. If the CAN controller receives a message and the NEWDAT bit is already set, the MSGLST bit in the **CANIFnMCTL** register is set to indicate that the previous data was lost. If the system requires an interrupt on successful reception of a frame, the RXIE bit of the **CANIFnMCTL** register should be set. In this case, the INTPND bit of the same register is set, causing the **CANINT** register to point to the message object that just received a message. The TXRQST bit of this message object should be cleared to prevent the transmission of a remote frame.

### 22.3.8 Receiving a Remote Frame

A remote frame contains no data, but instead specifies which object should be transmitted. When a remote frame is received, three different configurations of the matching message object have to be considered:

**Table 22-2. Message Object Configurations**

| Configuration in <b>CANIFnMCTL</b>                                                                                                                                                                                                                                                                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 1 (set the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame to enable transmission)</li> <li>■ UMASK = 1 or 0</li> </ul>                                                                           | At the reception of a matching remote frame, the TXRQST bit of this message object is set. The rest of the message object remains unchanged, and the controller automatically transfers the data in the message object as soon as possible.                                                                                                                                                                                                                                                                                                                                                                                       |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ UMASK = 0 (ignore mask in the <b>CANIFnMSKn</b> register)</li> </ul>                                             | At the reception of a matching remote frame, the TXRQST bit of this message object remains unchanged, and the remote frame is ignored. This remote frame is disabled, the data is not transferred and nothing indicates that the remote frame ever happened.                                                                                                                                                                                                                                                                                                                                                                      |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ UMASK = 1 (use mask (MSK, MXTD, and MDIR in the <b>CANIFnMSKn</b> register) for acceptance filtering)</li> </ul> | At the reception of a matching remote frame, the TXRQST bit of this message object is cleared. The arbitration and control field (ID + XTD + RMTEN + DLC) from the shift register is stored into the message object in the message RAM, and the NEWDAT bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This mode is useful for a remote data request from another CAN device for which the TM4C129DNCZAD controller does not have readily available data. The software must fill the data and answer the frame manually. |

### 22.3.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This prioritization is separate from that of the message identifier which is enforced by the CAN bus. As a result, if message object 1 and message object 2 both have valid messages to be transmitted, message object 1 is always transmitted first regardless of the message identifier in the message object itself.

#### 22.3.10 Configuring a Receive Message Object

The following steps illustrate how to configure a receive message object.

1. Program the **CAN IFn Command Mask (CANIFnCMASK)** register as described in the “Configuring a Transmit Message Object” on page 1480 section, except that the WRNRD bit is set to specify a write to the message RAM.
2. Program the **CANIFnMSK1** and **CANIFnMSK2** registers as described in the “Configuring a Transmit Message Object” on page 1480 section to configure which bits are used for acceptance filtering. Note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. Program the **CANIFnARB1** and **CANIFnARB2** registers as described in the “Configuring a Transmit Message Object” on page 1480 section to program XTD and ID bits for the message identifier to be received; set the MSGVAL bit to indicate a valid message; and clear the DIR bit to specify receive.
5. In the **CANIFnMCTL** register:
  - Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the RXIE bit to enable the INTPND bit to be set after a successful reception
  - Clear the RMTEN bit to leave the TXRQST bit unchanged
  - Set the EOB bit for a single message object
  - Configure the DLC[3:0] field to specify the size of the data frame

Take care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
6. Program the number of the message object to be received in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. Reception of the message object begins as soon as a matching frame is available on the CAN bus.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes in the **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** register. Byte 0 of the CAN data frame is stored in DATA[7:0] in the **CANIFnDA1** register. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are received by a message object. The UMASK bit in the **CANIFnMCTL** register enables the MSK bits in the **CANIFnMSKn** register to filter which frames are received. The MXTD bit in the **CANIFnMSK2** register should be set if only 29-bit extended identifiers are expected by this message object.

### 22.3.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the **CANIFnCMSK** register and then writes the number of the message object to the **CANIFnCRQ** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSKn**, **CANIFnARBn**, and **CANIFnMCTL**). Additionally, the NEWDAT and INTPND bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt generated by this message object.

If the message object uses masks for acceptance filtering, the **CANIFnARBn** registers show the full, unmasked ID for the received message.

The NEWDAT bit in the **CANIFnMCTL** register shows whether a new message has been received since the last time this message object was read. The MSGLST bit in the **CANIFnMCTL** register shows whether more than one message has been received since the last time this message object was read. MSGLST is not automatically cleared, and should be cleared by software after reading its status.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the TXRQST bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TXRQST bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

#### 22.3.11.1 Configuration of a FIFO Buffer

With the exception of the EOB bit in the **CANIFnMCTL** register, the configuration of receive message objects belonging to a FIFO buffer is the same as the configuration of a single receive message object (see "Configuring a Receive Message Object" on page 1483). To concatenate two or more message objects into a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest message object number is the first message object in a FIFO buffer. The EOB bit of all message objects of a FIFO buffer except the last one must be cleared. The EOB bit of the last message object of a FIFO buffer is set, indicating it is the last entry in the buffer.

#### 22.3.11.2 Reception of Messages with FIFO Buffers

Received messages with identifiers matching to a FIFO buffer are stored starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NEWDAT of the **CANIFnMCTL** register bit of this message object is set. By setting

NEWDAT while EOB is clear, the message object is locked and cannot be written to by the message handler until the CPU has cleared the NEWDAT bit. Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. Until all of the preceding message objects have been released by clearing the NEWDAT bit, all further messages for this FIFO buffer are written into the last message object of the FIFO buffer and therefore overwrite previous messages.

#### 22.3.11.3 Reading from a FIFO Buffer

When the CPU transfers the contents of a message object from a FIFO buffer by writing its number to the **CANIFnCRQ** register, the TXRQST and CLRINTPND bits in the **CANIFnCMSK** register should be set such that the NEWDAT and INTPEND bits in the **CANIFnMCTL** register are cleared after the read. The values of these bits in the **CANIFnMCTL** register always reflect the status of the message object before the bits are cleared. To assure the correct function of a FIFO buffer, the CPU should read out the message objects starting with the message object with the lowest message number. When reading from the FIFO buffer, the user should be aware that a new received message is placed in the message object with the lowest message number for which the NEWDAT bit of the **CANIFnMCTL** register is clear. As a result, the order of the received messages in the FIFO is not guaranteed. Figure 22-3 on page 1486 shows how a set of message objects which are concatenated to a FIFO Buffer can be handled by the CPU.

Figure 22-3. Message Objects in a FIFO Buffer

### 22.3.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. The status interrupt has the highest

priority. Among the message interrupts, the message object's interrupt with the lowest message number has the highest priority. A message interrupt is cleared by clearing the message object's INTPND bit in the **CANIFnMCTL** register or by reading the **CAN Status (CANSTS)** register. The status Interrupt is cleared by reading the **CANSTS** register.

The interrupt identifier INTID in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register reads as 0x0000. If the value of the INTID field is different from 0, then an interrupt is pending. If the IE bit is set in the **CANCTL** register, the interrupt line to the interrupt controller is active. The interrupt line remains active until the INTID field is 0, meaning that all interrupt sources have been cleared (the cause of the interrupt is reset), or until IE is cleared, which disables interrupts from the CAN controller.

The INTID field of the **CANINT** register points to the pending message interrupt with the highest interrupt priority. The SIE bit in the **CANCTL** register controls whether a change of the RXOK, TXOK, and LEC bits in the **CANSTS** register can cause an interrupt. The EIE bit in the **CANCTL** register controls whether a change of the BOFF and EWARN bits in the **CANSTS** register can cause an interrupt. The IE bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the interrupt controller. The **CANINT** register is updated even when the IE bit in the **CANCTL** register is clear, but the interrupt is not indicated to the CPU.

A value of 0x8000 in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register, indicating that either an error or status interrupt has been generated. A write access to the **CANSTS** register can clear the RXOK, TXOK, and LEC bits in that same register; however, the only way to clear the source of a status interrupt is to read the **CANSTS** register.

The source of an interrupt can be determined in two ways during interrupt handling. The first is to read the INTID bit in the **CANINT** register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and clear the message object's INTPND bit at the same time by setting the CLRINTPND bit in the **CANIFnCMSK** register. Once the INTPND bit has been cleared, the **CANINT** register contains the message number for the next message object with a pending interrupt.

### 22.3.13 Test Mode

A Test Mode is provided which allows various diagnostics to be performed. Test Mode is entered by setting the TEST bit in the **CANCTL** register. Once in Test Mode, the TX[1:0], LBACK, SILENT and BASIC bits in the **CAN Test (CANTST)** register can be used to put the CAN controller into the various diagnostic modes. The RX bit in the **CANTST** register allows monitoring of the CANnRX signal. All **CANTST** register functions are disabled when the TEST bit is cleared.

#### 22.3.13.1 Silent Mode

Silent Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames). The CAN Controller is put in Silent Mode setting the SILENT bit in the **CANTST** register. In Silent Mode, the CAN controller is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and cannot start a transmission. If the CAN Controller is required to send a dominant bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the CAN Controller monitors this dominant bit, although the CAN bus remains in recessive state.

### 22.3.13.2 Loopback Mode

Loopback mode is useful for self-test functions. In Loopback Mode, the CAN Controller internally routes the CANnTX signal on to the CANnRX signal and treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into the message buffer. The CAN Controller is put in Loopback Mode by setting the LBACK bit in the **CANTST** register. To be independent from external stimulation, the CAN Controller ignores acknowledge errors (a recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. The actual value of the CANnRX signal is disregarded by the CAN Controller. The transmitted messages can be monitored on the CANnTX signal.

### 22.3.13.3 Loopback Combined with Silent Mode

Loopback Mode and Silent Mode can be combined to allow the CAN Controller to be tested without affecting a running CAN system connected to the CANnTX and CANnRX signals. In this mode, the CANnRX signal is disconnected from the CAN Controller and the CANnTX signal is held recessive. This mode is enabled by setting both the LBACK and SILENT bits in the **CANTST** register.

### 22.3.13.4 Basic Mode

Basic Mode allows the CAN Controller to be operated without the Message RAM. In Basic Mode, The CANIF1 registers are used as the transmit buffer. The transmission of the contents of the IF1 registers is requested by setting the BUSY bit of the **CANIF1CRQ** register. The CANIF1 registers are locked while the BUSY bit is set. The BUSY bit indicates that a transmission is pending. As soon the CAN bus is idle, the CANIF1 registers are loaded into the shift register of the CAN Controller and transmission is started. When the transmission has completed, the BUSY bit is cleared and the locked CANIF1 registers are released. A pending transmission can be aborted at any time by clearing the BUSY bit in the **CANIF1CRQ** register while the CANIF1 registers are locked. If the CPU has cleared the BUSY bit, a possible retransmission in case of lost arbitration or an error is disabled.

The CANIF2 Registers are used as a receive buffer. After the reception of a message, the contents of the shift register are stored in the CANIF2 registers, without any acceptance filtering. Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read message object is initiated by setting the BUSY bit of the **CANIF2CRQ** register, the contents of the shift register are stored into the CANIF2 registers.

In Basic Mode, all message-object-related control and status bits and of the control bits of the **CANIFnCMSK** registers are not evaluated. The message number of the **CANIFnCRQ** registers is also not evaluated. In the **CANIF2MCTL** register, the NEWDAT and MSGLST bits retain their function, the DLC[3:0] field shows the received DLC, the other control bits are cleared.

Basic Mode is enabled by setting the BASIC bit in the **CANTST** register.

### 22.3.13.5 Transmit Control

Software can directly override control of the CANnTX signal in four different ways.

- CANnTX is controlled by the CAN Controller
- The sample point is driven on the CANnTX signal to monitor the bit timing
- CANnTX drives a low value
- CANnTX drives a high value

The last two functions, combined with the readable CAN receive pin CANnRX, can be used to check the physical layer of the CAN bus.

The Transmit Control function is enabled by programming the TX[1:0] field in the **CANTST** register. The three test functions for the CANnTX signal interfere with all CAN protocol functions. TX[1:0] must be cleared when CAN message transfer or Loopback Mode, Silent Mode, or Basic Mode are selected.

### 22.3.14 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

### 22.3.15 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 22-4 on page 1490): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 22-3 on page 1490). The length of the time quantum ( $t_q$ ), which is the basic time unit of the bit time, is defined by the CAN controller's input clock ( $f_{sys}$ ) and the Baud Rate Prescaler (BRP):

$$t_q = \text{BRP} / f_{sys}$$

The  $f_{sys}$  input clock is the system clock frequency as configured by the **RSCLKCFG** register (see page 279).

The Synchronization Segment Sync is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of Sync and the Sync is called the phase error of that edge.

The Propagation Time Segment Prop is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments Phase1 and Phase2 surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 22-4. CAN Bit Time

Table 22-3. CAN Protocol Ranges<sup>a</sup>

| Parameter | Range          | Remark                                                                                                              |
|-----------|----------------|---------------------------------------------------------------------------------------------------------------------|
| BRP       | [1 .. 64]      | Defines the length of the time quantum $t_q$ . The <b>CANBRPE</b> register can be used to extend the range to 1024. |
| Sync      | 1 $t_q$        | Fixed length, synchronization of bus input to system clock                                                          |
| Prop      | [1 .. 8] $t_q$ | Compensates for the physical delay times                                                                            |
| Phase1    | [1 .. 8] $t_q$ | May be lengthened temporarily by synchronization                                                                    |
| Phase2    | [1 .. 8] $t_q$ | May be shortened temporarily by synchronization                                                                     |
| SJW       | [1 .. 4] $t_q$ | May not be longer than either Phase Buffer Segment                                                                  |

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. In the **CANBIT** register, the four components TSEG2, TSEG1, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits in the SJW bit field. Table 22-4 shows the relationship between the **CANBIT** register values and the parameters.

Table 22-4. CANBIT Register Values

| CANBIT Register Field | Setting           |
|-----------------------|-------------------|
| TSEG2                 | Phase2 - 1        |
| TSEG1                 | Prop + Phase1 - 1 |
| SJW                   | SJW - 1           |
| BRP                   | BRP               |

Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync + Prop + Phase1 + Phase2] \times t_q$$

The data in the **CANBIT** register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by the BRP field) defines the length of the time quantum, the basic time

unit of the bit time; the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. In addition, the controller generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. The bit value is received or transmitted at the sample point. The information processing time (IPT) is the time after the sample point needed to calculate the next bit to be transmitted on the CAN bus. The IPT includes any of the following: retrieving the next data bit, handling a CRC bit, determining if bit stuffing is required, generating an error flag or simply going idle.

The IPT is application-specific but may not be longer than  $2 t_q$ ; the CAN's IPT is  $0 t_q$ . Its length is the lower limit of the programmed length of Phase2. In case of synchronization, Phase2 may be shortened to a value less than IPT, which does not affect bus timing.

### 22.3.16 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a required bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the required bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is Prop. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

Sync is  $1 t_q$  long (fixed), which leaves (bit time - Prop -  $1 t_q$ ) for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length, that is, Phase2 = Phase1, else Phase2 = Phase1 + 1.

The minimum nominal length of Phase2 has to be regarded as well. Phase2 may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of  $[0..2] t_q$ .

The length of the synchronization jump width is set to the least of 4, Phase1 or Phase2.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- $df$  = Maximum tolerance of oscillator frequency
- $f_{osc}$  = Actual oscillator frequency
- $f_{nom}$  = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq \frac{(Phase\_seg1, Phase\_seg2) \min}{2 \times (13 \times t_{bit} - Phase\_Seg2)}$$

$$df_{max} = 2 \times df \times f_{nom}$$

where:

- Phase1 and Phase2 are from Table 22-3 on page 1490
- $t_{bit}$  = Bit Time
- $df_{max}$  = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

### 22.3.16.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, and the bit rate is 1 Mbps.

$$\text{bit time} = 1 \mu\text{s} = n * t_q = 5 * t_q$$

$$t_q = 200 \text{ ns}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 200\text{E}-9 * 25\text{E}6 = 5$$

$$t_{\text{Sync}} = 1 * t_q = 200 \text{ ns}$$

\\fixed at 1 time quanta

delay of bus driver 50 ns

delay of receiver circuit 30 ns

delay of bus line (40m) 220 ns

$$t_{\text{Prop}} 400 \text{ ns} = 2 * t_q$$

\\400 is next integer multiple of  $t_q$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{TSeg1}} + t_{\text{TSeg2}} = 5 * t_q$$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{Prop}} + t_{\text{Phase 1}} + t_{\text{Phase 2}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = \text{bit time} - t_{\text{Sync}} - t_{\text{Prop}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = (5 * t_q) - (1 * t_q) - (2 * t_q)$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = 2 * t_q$$

$$t_{\text{Phase1}} = 1 * t_q$$

$$t_{\text{Phase2}} = 1 * t_q$$

\\tPhase2 = tPhase1

$$\begin{aligned} tTSeg1 &= tProp + tPhase1 \\ tTSeg1 &= (2 * t_q) + (1 * t_q) \\ tTSeg1 &= 3 * t_q \end{aligned}$$

$$\begin{aligned} tTSeg2 &= tPhase2 \\ tTSeg2 &= (\text{Information Processing Time} + 1) * t_q \\ tTSeg2 &= 1 * t_q \quad \backslash\backslash \text{Assumes IPT}=0 \end{aligned}$$

$$tSJW = 1 * t_q \quad \backslash\backslash \text{Least of 4, Phase1 and Phase2}$$

In the above example, the bit field values for the **CANBIT** register are:

|       |                                           |
|-------|-------------------------------------------|
| TSEG2 | = TSeg2 -1<br>= 1-1<br>= 0                |
| TSEG1 | = TSeg1 -1<br>= 3-1<br>= 2                |
| SJW   | = SJW -1<br>= 1-1<br>= 0                  |
| BRP   | = Baud rate prescaler - 1<br>= 5-1<br>= 4 |

The final value programmed into the **CANBIT** register = 0x0204.

### 22.3.16.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of the CAN clock is 50 MHz, and the bit rate is 100 Kbps.

$$\begin{aligned} \text{bit time} &= 10 \mu\text{s} = n * t_q = 10 * t_q \\ t_q &= 1 \mu\text{s} \\ t_q &= (\text{Baud rate Prescaler}) / \text{CAN Clock} \\ \text{Baud rate Prescaler} &= t_q * \text{CAN Clock} \\ \text{Baud rate Prescaler} &= 1\text{E-}6 * 50\text{E}6 = 50 \end{aligned}$$

$$tSync = 1 * t_q = 1 \mu\text{s} \quad \backslash\backslash \text{fixed at 1 time quanta}$$

$$\begin{aligned} \text{delay of bus driver} &200 \text{ ns} \\ \text{delay of receiver circuit} &80 \text{ ns} \\ \text{delay of bus line (40m)} &220 \text{ ns} \\ tProp \ 1 \mu\text{s} &= 1 * t_q \quad \backslash\backslash 1 \mu\text{s is next integer multiple of } t_q \end{aligned}$$

$$\begin{aligned} \text{bit time} &= tSync + tTSeg1 + tTSeg2 = 10 * t_q \\ \text{bit time} &= tSync + tProp + tPhase 1 + tPhase2 \\ tPhase 1 + tPhase2 &= \text{bit time} - tSync - tProp \\ tPhase 1 + tPhase2 &= (10 * t_q) - (1 * t_q) - (1 * t_q) \\ tPhase 1 + tPhase2 &= 8 * t_q \\ tPhase1 &= 4 * t_q \\ tPhase2 &= 4 * t_q \quad \backslash\backslash tPhase1 = tPhase2 \end{aligned}$$

$$\begin{aligned}
 tTSeg1 &= tProp + tPhase1 \\
 tTSeg1 &= (1 * t_q) + (4 * t_q) \\
 tTSeg1 &= 5 * t_q \\
 tTSeg2 &= tPhase2 \\
 tTSeg2 &= (Information Processing Time + 4) * t_q \\
 tTSeg2 &= 4 * t_q \quad \quad \quad \backslash\backslash \text{Assumes IPT}=0 \\
 \\ 
 tSJW &= 4 * t_q \quad \quad \quad \backslash\backslash \text{Least of 4, Phase1, and Phase2}
 \end{aligned}$$

|       |                                            |
|-------|--------------------------------------------|
| TSEG2 | = TSeg2 -1<br>= 4-1<br>= 3                 |
| TSEG1 | = TSeg1 -1<br>= 5-1<br>= 4                 |
| SJW   | = SJW -1<br>= 4-1<br>= 3                   |
| BRP   | = Baud rate prescaler - 1<br>= 50-1<br>=49 |

The final value programmed into the **CANBIT** register = 0x34F1.

## 22.4 Register Map

Table 22-5 on page 1494 lists the registers. All addresses given are relative to the CAN base address of:

- CAN0: 0x4004.0000
- CAN1: 0x4004.1000

Note that the CAN controller clock must be enabled before the registers can be programmed (see page 398). There must be a delay of 3 system clocks after the CAN module clock is enabled before any CAN module registers are accessed.

**Table 22-5. CAN Register Map**

| Offset | Name      | Type | Reset       | Description                       | See page |
|--------|-----------|------|-------------|-----------------------------------|----------|
| 0x000  | CANCTL    | RW   | 0x0000.0001 | CAN Control                       | 1497     |

## 22.5 CAN Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in

the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

## Register 1: CAN Control (CANCTL), offset 0x000

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or clearing INIT. If the device goes bus-off, it sets INIT, stopping all bus activities. Once INIT has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 \* 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after INIT is cleared, each time a sequence of 11 High bits has been monitored, a BITERROR0 code is written to the **CANSTS** register (the LEC field = 0x5), enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

### CAN Control (CANCTL)

**Register 2: CAN Status (CANSTS), offset 0x004**

**Important:** This register is read-sensitive. See the register description for details.

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared when a message has been transferred (reception or transmission) without error. The unused error code 0x7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An error interrupt is generated by the BOFF and EWARN bits, and a status interrupt is generated by the RXOK, TXOK, and LEC bits, if the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPASS bit or a write to the RXOK, TXOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

**CAN Status (CANSTS)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x004

Type RW, reset 0x0000.0000

When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |  | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0). | 0x5 | Bit 0 Error |  | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1). |  | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus. | 0x6 | CRC Error |  | The CRC checksum was incorrect in the received message, indicating that the calculated value received did not match the calculated CRC of the data. | 0x7 | No Event |  | When the LEC bit shows this value, no CAN bus event was detected since this value was written to the LEC field. |
| Value     | Description                                                                                                                                                                                                                                                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | When a message is transmitted, the CAN controller monitors the data lines to detect any conflicts. When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0).                                                                                                                                                    |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1).                                                                                                                                                   |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus.                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

**Register 3: CAN Error Counter (CANERR), offset 0x008**

This register contains the error counter values, which can be used to analyze the cause of an error.

**CAN Error Counter (CANERR)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x008

Type RO, reset 0x0000.0000

## Register 4: CAN Bit Timing (CANBIT), offset 0x00C

This register is used to program the bit width and bit quantum. Values are programmed to the system clock frequency. This register is write-enabled by setting the CCE and INIT bits in the **CANCTL** register. See “Bit Time and Bit Rate” on page 1489 for more information.

| 14:12     | TSEG2    | RW   | 0x2    | Time Segment after Sample Point<br>0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x2 means that 3 (2+1) bit time quanta are defined for Phase2 (see Figure 22-4 on page 1490). The bit time quanta is defined by the BRP field.                                                                                                                                                                 |
| 11:8      | TSEG1    | RW   | 0x3    | Time Segment Before Sample Point<br>0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x3 means that 4 (3+1) bit time quanta are defined for Phase1 (see Figure 22-4 on page 1490). The bit time quanta is defined by the BRP field.                                                                                                                                                                |
| 7:6       | SJW      | RW   | 0x0    | (Re)Synchronization Jump Width<br>0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of TSEG2 or TSEG1 by the value in SJW. So the reset value of 0 adjusts the length by 1 bit time quanta.                                                                                                                       |
| 5:0       | BRP      | RW   | 0x1    | Baud Rate Prescaler<br>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum.<br>0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>BRP defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1).<br>The <b>CANBRPE</b> register can be used to further divide the bit time. |

Register 5: CAN Interrupt (CANINT), offset 0x010

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the INTID field is not 0x0000 (the default) and the IE bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the INTID field is cleared by reading the **CANSTS** register, or until the IE bit in the **CANCTL** register is cleared.

**Note:** Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

CAN Interrupt (CANINT)

**Register 6: CAN Test (CANTST), offset 0x014**

This register is used for self-test and external pin access. It is write-enabled by setting the TEST bit in the **CANCTL** register. Different test functions may be combined, however, CAN transfers are affected if the TX bits in this register are not zero.

**CAN Test (CANTST)**

**Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020****Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080**

A message transfer is started as soon as there is a write of the message object number to the MNUM field when the TXRQST bit in the **CANIF1MCTL** register is set. With this write operation, the BUSY bit is automatically set to indicate that a transfer between the CAN Interface Registers and the internal message RAM is in progress. After a wait time of 3 to 6 CAN\_CLK periods, the transfer between the interface register and the message RAM completes, which then clears the BUSY bit.

**CAN IFn Command Request (CANIFnCRQ)**

**Register 10: CAN IF1 Command Mask (CANIF1CMSK), offset 0x024****Register 11: CAN IF2 Command Mask (CANIF2CMSK), offset 0x084**

Reading the Command Mask registers provides status for various functions. Writing to the Command Mask registers specifies the transfer direction and selects which buffer registers are the source or target of the data transfer.

Note that when a read from the message object buffer occurs when the WRNRD bit is clear and the CLRINTPND and/or NEWDAT bits are set, the interrupt pending and/or new data flags in the message object buffer are cleared.

**CAN IFn Command Mask (CANIFnCMSK)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x024

Type RW, reset 0x0000.0000

Register 12: CAN IF1 Mask 1 (CANIF1MSK1), offset 0x028

Register 13: CAN IF2 Mask 1 (CANIF2MSK1), offset 0x088

The mask information provided in this register accompanies the data (**CANIFnDAn**), arbitration information (**CANIFnARBn**), and control information (**CANIFnMCTL**) to the message object in the message RAM. The mask is used with the ID bit in the **CANIFnARBn** register for acceptance filtering. Additional mask information is contained in the **CANIFnMSK2** register.

CAN IFn Mask 1 (CANIFnMSK1)

CAN0 base: 0x4004.0000  
CAN1 base: 0x4004.1000  
Offset 0x028  
Type RW, reset 0x0000.FFFF

|-------|---------------------------------------------------------------------------------------------------------------|
| 0     | The message object is ignored by the message handler.                                                         |
| 1     | The message object is configured and ready to be considered by the message handler within the CAN controller. |

All unused message objects should have this bit cleared during initialization and before clearing the INIT bit in the **CANCTL** register. The MSGVAL bit must also be cleared before any of the following bits are modified or if the message object is no longer required: the ID fields in the **CANIFnARBn** registers, the XTD and DIR bits in the **CANIFnARB2** register, or the DLC field in the **CANIFnMCTL** register.

When the TXRQST bit in the <b>CANIFnMCTL</b> register is set, a remote frame with the identifier of this message object is received. On reception of a data frame with matching identifier, that message is stored in this message object.       |
|           |      |      |       | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Transmit. When the TXRQST bit in the <b>CANIFnMCTL</b> register is set, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TXRQST bit of this message object is set (if RMTEN=1). |

| 0x0-0x8   | Specifies the number of bytes in the data frame.                                                |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |       |             |         |                                                                                                 |         |                                                                |
| 0x9-0xF   | Defaults to a data frame with 8 bytes.                                                          |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |       |             |         |                                                                                                 |         |                                                                |

**Register 22: CAN IF1 Data A1 (CANIF1DA1), offset 0x03C**

**Register 23: CAN IF1 Data A2 (CANIF1DA2), offset 0x040**

**Register 24: CAN IF1 Data B1 (CANIF1DB1), offset 0x044**

**Register 25: CAN IF1 Data B2 (CANIF1DB2), offset 0x048**

**Register 26: CAN IF2 Data A1 (CANIF2DA1), offset 0x09C**

**Register 27: CAN IF2 Data A2 (CANIF2DA2), offset 0x0A0**

**Register 28: CAN IF2 Data B1 (CANIF2DB1), offset 0x0A4**

**Register 29: CAN IF2 Data B2 (CANIF2DB2), offset 0x0A8**

These registers contain the data to be sent or that has been received. In a CAN data frame, data byte 0 is the first byte to be transmitted or received and data byte 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte is transmitted first.

**Register 30: CAN Transmission Request 1 (CANTXRQ1), offset 0x100****Register 31: CAN Transmission Request 2 (CANTXRQ2), offset 0x104**

The **CANTXRQ1** and **CANTXRQ2** registers hold the TXRQST bits of the 32 message objects. By reading out these bits, the CPU can check which message object has a transmission request pending. The TXRQST bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a remote frame, or (3) the message handler state machine after a successful transmission.

The **CANTXRQ1** register contains the TXRQST bits of the first 16 message objects in the message RAM; the **CANTXRQ2** register contains the TXRQST bits of the second 16 message objects.

Register 34: CAN Message 1 Interrupt Pending (CANMSG1INT), offset 0x140

Register 35: CAN Message 2 Interrupt Pending (CANMSG2INT), offset 0x144

The **CANMSG1INT** and **CANMSG2INT** registers hold the INTPND bits of the 32 message objects. By reading these bits, the CPU can check which message object has an interrupt pending. The INTPND bit of a specific message object can be changed through two sources: (1) the CPU via the **CANIFnMCTL** register, or (2) the message handler state machine after the reception or transmission of a frame.

This field is also encoded in the **CANINT** register.

The **CANMSG1INT** register contains the INTPND bits of the first 16 message objects in the message RAM; the **CANMSG2INT** register contains the INTPND bits of the second 16 message objects.

**Register 36: CAN Message 1 Valid (CANMSG1VAL), offset 0x160****Register 37: CAN Message 2 Valid (CANMSG2VAL), offset 0x164**

The **CANMSG1VAL** and **CANMSG2VAL** registers hold the MSGVAL bits of the 32 message objects. By reading these bits, the CPU can check which message object is valid. The message valid bit of a specific message object can be changed with the **CANIFnARB2** register.

The **CANMSG1VAL** register contains the MSGVAL bits of the first 16 message objects in the message RAM; the **CANMSG2VAL** register contains the MSGVAL bits of the second 16 message objects in the message RAM.

**CAN Message n Valid (CANMSGnVAL)**

## 23 Ethernet Controller

The Ethernet Controller has the following features:

- Conforms to the IEEE 802.3 specification
  - 10BASE-T/100BASE-TX IEEE-802.3 compliant
  - Supports 10/100 Mbps data transmission rates
  - Supports full-duplex and half-duplex (CSMA/CD) operation
  - Supports flow control and back pressure
  - Full-featured and enhanced auto-negotiation
  - Supports IEEE 802.1Q VLAN tag detection
- Conforms to IEEE 1588-2002 Timestamp Precision Time Protocol (PTP) protocol and the IEEE 1588-2008 Advanced Timestamp specification
  - Transmit and Receive frame time stamping
  - Precision Time Protocol
  - Flexible pulse per second output
  - Supports coarse and fine correction methods
- Multiple addressing modes
  - Four MAC address filters
  - Programmable 64-bit Hash Filter for multicast address filtering
  - Promiscuous mode support
- Processor offloading
  - Programmable insertion (TX) or deletion (RX) of preamble and start-of-frame data
  - Programmable generation (TX) or deletion (RX) of CRC and pad data
  - IP header and hardware checksum checking (IPv4, IPv6, TCP/UDP/ICMP)
- Highly configurable
  - Supports network statistics with RMON/MIB counters
  - Supports Magic Packet and wakeup frames
- Efficient transfers using integrated Direct Memory Access (DMA)
  - Dual-buffer (ring) or linked-list (chained) descriptors
  - Round-robin or fixed priority arbitration between TX/RX

- Descriptors support up to 8 kB transfer blocks size
- Programmable interrupts for flexible system implementation
- MII and RMI interface support

## 23.1 Block Diagram

Figure 23-1 on page 1527 shows the block diagram of the Ethernet MAC:

Figure 23-1. Ethernet MAC

## 23.2 Signal Description

The following table lists the external signals of the Ethernet Controller and describes the function of each. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these Ethernet module signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to assign the Ethernet signals. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 788) to assign the Ethernet signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 741. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

Table 23-1. Ethernet Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                                     |
|----------|------------|--------------------------|----------|-------------|-------------------------------------------------|

## 23.3 Functional Description

The Ethernet Controller is made up of the following sub-modules:

- Clock Control
- MII/RMII Interface Module
- DMA Controller
- Transmit/Receive Controller (TX/RX Controller)
- Media Access Controller (MAC)
- AHB Bus Interface

The following sections describe the features and functions of each sub-module.

### 23.3.1 Ethernet Clock Control

Available clock sources are dependent on the interface chosen. The following sections describe the clock control for the various interfaces.

#### 23.3.1.1 MII Interface

Four clock inputs are driven into the Ethernet MAC when the MII configuration is enabled. The clocks are described as follows:

- Gated system clock (SYSCLK): The SYSCLK signal acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SYSCLK frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module. Refer to “System Control” on page 224 for more information on programming SYSCLK and enabling the Ethernet MAC.
- MOSC: A gated version of the MOSC clock is provided as the Precision Time Protocol (PTP) reference clock (PTPREF\_CLK). The MOSC clock source can be a single-ended source on the OSC0 pin or a crystal on the OSC0 and OSC1 pins. When advanced timestamping is used and the Precision Timer Protocol (PTP) module has been enabled by setting the PTPCEN bit in the **EMACCC** register, the MOSC drives PTPREF\_CLK. PTPREF\_CLK has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. Refer to “IEEE 1588 and Advanced Timestamp Function” on page 1570 for more information.
- EN0RXCK: This clock signal is driven by the external PHY oscillator and is either 2.5 or 25 MHz depending on whether the device is operating at 10 Mbps or 100 Mbps.
- EN0TXCK: This clock signal is driven by the external PHY oscillator and is either 2.5 or 25 MHz depending on whether the device is operating at 10 Mbps or 100 Mbps.

Figure 23-2 on page 1529 depicts the clock inputs for an MII interface.

**Figure 23-2. MII Clock Structure**

### 23.3.1.2 RMII Interface

There are three clock sources that interface to the Ethernet MAC in an RMII configuration:

- Gated system clock (SYSCLK): The SYSCLK signal acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SYSCLK frequency for Run, Sleep and Deep

Sleep mode is programmed in the System Control module. Refer to “System Control” on page 224 for more information on programming SYSCLK and enabling the Ethernet MAC.

- **MOSC:** A gated version of the MOSC clock is provided as the Precision Time Protocol (PTP) reference clock (PTPREF\_CLK). The MOSC clock source can be a single-ended source on the OSC0 pin or a crystal on the OSC0 and OSC1 pins. When advanced timestamping is used and the PTP module has been enabled by setting the PTPCEN bit in the **EMACCC** register, the MOSC drives PTPREF\_CLK. PTPREF\_CLK has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. Refer to “IEEE 1588 and Advanced Timestamp Function” on page 1570 for more information.
- **EN0REF\_CLK:** When using RMII, a 50 MHz external reference clock must drive the EN0REF\_CLK input signal and the external PHY. Depending on the configuration of the FES bit in the **Ethernet MAC Configuration (EMACCFG)** register, the reference clock input (EN0REF\_CLK) is divided by 20 for 10 Mbps or 2 for 100 Mbps operation and used as the clock for receive and transmit data.

Figure 23-3 on page 1530 depicts the clock inputs to the RMII clock interface.

**Figure 23-3. RMII Clock Structure**

### 23.3.2 MII/RMII Interface Signals

The MAC Module has the capability of providing an MII or RMII interface depending on the interface selected in the **Ethernet MAC Peripheral Configuration (EMACPC)** register, at offset 0xFC4. Except for EN0REF\_CLK, the signals used for RMII mode are a subset of the MII interface signals. Thus, Table 23-2 on page 1531 details the MII signals that are used in RMII mode and the RMII function to which they correspond. In addition, the GPIO pin they are muxed with is listed.

**Table 23-2. MII and RMII Interface Signals**

| MII Signal | RMII       | RMII Standard Name and Function                                             | GPIO        |
|------------|------------|-----------------------------------------------------------------------------|-------------|
| N/A        | EN0REF_CLK | REF_CLK: Synchronous clock reference for receive, transmit and control      | PM4         |
| EN0TXCK    | Not Used   | N/A                                                                         | PG2         |
| EN0TD3     | Not Used   | N/A                                                                         | PK7         |
| EN0TXD2    | Not Used   | N/A                                                                         | PK6         |
| EN0TXD1    | EN0TXD1    | TXD1: Transmit Data 1                                                       | PG5/PS5     |
| EN0TXD0    | EN0TXD0    | TXD0: Transmit Data 0                                                       | PG4/PS4     |
| EN0TXEN    | EN0TXEN    | TEX_EN: Transmit Enable                                                     | PG3/PR7     |
| EN0TXER    | Not Used   | N/A                                                                         | PN6         |

### 23.3.3 DMA Controller

The Ethernet Controller's integrated DMA is used to optimize data transfer between the MAC and system SRAM memory. The DMA has independent transmit and receive engines.

The DMA transmit engine transfers data from system memory to the Ethernet TX/RX Controller, while the receive engine transfers data from the RX FIFO to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. Fixed burst lengths of 1, 4, 8, or 16 words are supported along with re-initiation of bursts when retry or burst termination responses occur. For a burst retry, if the remaining address count is greater than 1 and the RIB bit in the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)** register is clear, then the transfer is resends data with in one continuous burst. When one transfer is left, it is done as a single burst and the transaction is terminated immediately afterward. If the RIB bit in the **EMACDMABUSMOD** register is set, the DMA sends the remaining data in fixed burst sizes of 1, 4, 8, or 16 words.

The application may also choose between solely fixed bursts or mixed bursts by the DMA. If the MB bit is set and the FB bit is clear in the **EMACDMABUSMOD** register, then the DMA uses fixed bursts for burst sizes less than 16 and a full, non-divided burst for lengths greater than 16. Fixed burst lengths allow for more DMA bus arbitration with other masters. Maximum burst transfer lengths can

be programmed for both the receive and transmit channels of the DMA through the PBL, RPBL and 8xPBL bit fields in the **EMACDMABUSMOD** register.

The DMA Controller requests a read transfer only when it can accept the received burst data completely. Data read from the bus is always pushed into the DMA without any delay or busy cycles. The DMA requests write transfers only when it has sufficient data to transfer the burst completely. When operating in fixed burst length mode, the DMA interface continues to burst with dummy data until the specified length is completed. The Ethernet controller can be programmed to interrupt the CPU in situations such as Frame Transmit and Receive transfer completion, and other normal/error conditions.

The integrated Ethernet DMA communicates through two data structures:

- Control and Status registers
- Descriptor lists and data buffers.

The DMA writes data frames received by the MAC to the receive buffer in system memory and transfers data frames for transmission from system memory to the MAC. Descriptors that reside in the system memory act as pointers to these buffers.

There are two descriptor lists: one for reception and one for transmission. The base address of each list is written into the **Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR)** register at offset 0xC0C and the **Ethernet Mac Transmit Descriptor List Address (EMACTXDLADDR)** register at offset 0xC10, respectively. Three types of descriptor formats are supported in the MAC module:

- Normal (4 words in length)
- Alternate (Used for IEEE1588-2005 Timestamp; 4 words in length, but last two words are used for timestamp values)
- Enhanced (8 words in length; used when optional modules are enabled in application)

These are described in more detail in “Descriptors” on page 1544. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by enabling second address chaining in both the Receive and Transmit descriptors (RDES1[24] and TDES1[24]) for normal descriptor formats. For enhanced descriptors, the second chaining bits are RDES[14] and TDES[20]. The descriptor lists reside in the SRAM memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used at different physical addresses rather than contiguous buffers in memory.

The data buffer also resides in the physical memory space and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data and buffer status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when the end of frame is detected. Data chaining can be enabled or disabled through the descriptors.

**Note:** The EMAC DMA Controller only has access to internal system SRAM memory.

### 23.3.3.1 Burst Access

The DMA attempts to execute fixed length Burst transfers if the FB bit is set in the **EMACDMABUSMOD** register. The maximum burst length is indicated and limited by the PBL field

in the **EMACDMABUSMOD** register. The Receive and Transmit descriptors are always accessed in the maximum possible (limited by PBL) burst-size for the 16- bytes to be read.

The TX DMA initiates a transfer only when there is sufficient space in the FIFO to accommodate the configured burst or remaining bytes of the end of a frame. When the DMA is configured for fixed-length burst, it transfers data using the best combination of fixed burst sizes of 4, 8, or 16 and single transactions. Otherwise when the FB bit is clear in the **EMACDMABUSMOD** register, the DMA transfers data as a continuous undefined burst and SINGLE transactions.

The RX DMA initiates a data transfer only when sufficient data to accommodate the configured burst is available in RX FIFO or when the end of frame (when it is less than the configured burst length) is detected in the RX FIFO. The DMA indicates the start address and the number of transfers required to the system. When the FB bit is set in the **EMACDMABUSMOD** register, then it transfers data using the best combination of fixed burst sizes of 4, 8, or 16 and single transactions. If the end-of frame is reached before the fixed-burst ends, then dummy transfers are performed in order to complete the fixed-burst. Otherwise, if the FB bit is clear, the DMA transfers data using INCR (undefined length) and SINGLE transactions. When the DMA is configured for address-aligned transfers, both DMA engines ensure that the first burst transfer on the system bus is less than or equal to the size of the configured PBL in the **EMACDMABUSMOD** register. Thus, all subsequent transfers start at an address that is aligned to the configured PBL. The DMA can only align the address for burst transfers up to size 16 because only bursts of 16 are supported.

### 23.3.3.2 Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on the start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers, with address aligned to the bus width and dummy data (old data) in the byte lanes that are not valid. This typically happens during the transfer of the beginning or end of an Ethernet frame. The software driver should discard the dummy bytes based on the start address of the buffer and size of the frame.

For example, if the transmit buffer address is 0x0000.0FF2, and 15 bytes need to be transferred, then the DMA reads five full words from address 0x0000.0FF0, but when transferring data to the TX FIFO, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the TX FIFO, unless it is the end of frame.

If the receive buffer address is 0x0000.0FF2 and 15 bytes of a received frame need to be transferred, then the DMA writes 5 full words from address 0x0000.0FF0. However, the first 2 bytes of first transfer and the last three bytes of the fifth transfer have dummy data. The DMA considers the offset address only if it is the first Receive buffer of the frame. The DMA ignores the offset address and performs full word writes for the middle and the last Receive buffer of the frame.

### 23.3.3.3 Buffer Size Calculations

The DMA does not update the size fields in the Transmit and Receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations. The TX DMA transfers the exact number of bytes (indicated by buffer size field of TDES1) to the MAC. If a descriptor is marked as first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame (SOF). If a descriptor is marked as last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of frame (EOF).

The RX DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the RX/TX Controller. If a descriptor is not marked as last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The

offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The Receive DMA always transfers the start of next frame with a new descriptor.

**Note:** Even when the start address of a receive buffer is not aligned to the data width of 32-bit system bus, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1,024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the Receive descriptor to have a 0x1002 offset. The Receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual useful space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes, because of the start address offset.

#### 23.3.3.4 DMA Arbiter

The arbiter inside the DMA module performs the arbitration between the Transmit and Receive channel accesses. The DMA can be configured to arbitrate in a round-robin or fixed-priority configuration. When the DA bit of the **EMACDMABUSMOD** register is clear, the DMA arbiter allocates the data bus in the ratio set by the PR bit field of the **EMACDMABUSMOD** register when both the TX and RX DMA request access at the same time. When the DA bit is set, the RX DMA always has priority over the TX DMA for data access by default. However if the TXPR bit of the **EMACDMABUSMOD** register is also set, then the TX DMA always gets priority over the RX DMA.

#### 23.3.3.5 DMA Transmission Operation

The following sections describe the modes of the transmit operation.

##### ***TX DMA Default Operation***

The TX DMA engine in default mode, operates as follows:

1. The CPU configures the transmit descriptor (TDES0-TDES3) and sets the OWN bit (TDES0[31]) after setting up the corresponding data buffers with the Ethernet frame.
2. When the ST bit of the **Ethernet MAC DMA Operation Mode (EMACDMAOPMODE)** register, offset 0xC18, is set the DMA enters the RUN state.
3. While in RUN state, the DMA polls the Transmit Descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the CPU (TDES0[31]=0), or if an error condition occurs, transmission is suspended and both the Transmit Buffer Unavailable (TU) bit and the Normal Interrupt Summary (NIS) bit are set in the **Ethernet MAC DMA Interrupt Status (EMACDMARIS)** register, offset 0xC14. The transmit engine then proceeds to Step 9.
4. If the acquired descriptor is flagged as owned by the DMA (TDES0[31]=1), the DMA decodes the transmit data buffer address from the acquired descriptor.
5. If the acquired descriptor is flagged as owned by DMA (TDES0[31] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
6. The DMA fetches the transmit data from system memory and transfers the data to the TX/RX Controller for transmission.

7. If the Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3, 4, and 5 are repeated until the end of the Ethernet frame data is transferred to the TX/RX Controller.
8. When frame transmission is complete, if IEEE 1588 timestamping was enabled for the frame (as indicated in the transmit status) the timestamp value is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. For Enhanced descriptors, the timestamp value is written into TDES6 and TDES7. The status information is then written to this transmit descriptor (TDES0). Because the OWN bit is cleared during this step, the CPU now owns this descriptor. If timestamping was not enabled for this frame, the DMA does not alter the contents of TDES2/TDES3 or TDES6/TDES7 depending on the descriptor configuration chosen.
9. The Transmit Interrupt (TI) bit is set in the **EMACDMARIS** register after transmission completion of a frame that has Interrupt on Completion set in its last descriptor. The Interrupt on Completion bit resides in TDES[31] for normal descriptors and TDES0[30] for alternate descriptors. The DMA engine then returns to Step 3.
10. In the suspend state, the DMA tries to reacquire the descriptor (and thereby return to Step 3) when it receives a transmit poll demand in the **Ethernet MAC Transmit Poll Demand (EMACTXPOLLD)** register, offset 0xC04, and the Underflow Interrupt Status (UNF) bit is cleared in the **EMACDMARIS** register. If the CPU stopped the DMA by clearing the ST bit of the **EMACDMAOPMODE** register, the DMA enters the STOP state.

Figure 23-4 on page 1536 shows the flow for the TX DMA default operation.

Figure 23-4. TX DMA Default Operation Using Normal Descriptors

If using Enhanced Descriptors, TDES2 and TDES3 are replaced with TDES6 and TDES7.

**TX DMA OSF Mode Operation**

While in the RUN state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first if the OSF bit of the **EMACDMAOPMODE** register is set. As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information.

In Operate on Second Frame (OSF) mode, the RUN state TX DMA operates in the following sequence:

1. The DMA operates as described in Steps 1 to 6 (see page 1534).
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into SUSPEND mode and skips to 7.
4. The DMA fetches the Transmit frame from system memory and transfers the frame until the end of the frame data is reached. It closes the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the previous frame's frame transmission status and times tamp. When the status is available, the DMA writes the timestamp to TDES2 and TDES3, if such timestamp was captured (as indicated by a status bit). If enhanced descriptors are being used, this information is written in TDES6 and TDES7. The DMA then writes the status, with a cleared OWN bit, to the corresponding TDES0, thus closing the descriptor. If timestamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3 (or TDES6/7 for enhanced descriptors).
6. If enabled, the Transmit interrupt (TI) bit is set in the **EMACDMARIS** register, the DMA fetches the next descriptor and then proceeds to 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into SUSPEND mode
7. In SUSPEND mode, if a pending status and timestamp are received, the DMA writes the timestamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. For enhanced descriptor use, the timestamp is written to TDES6 and TDES7 and the status is written to TDES0. It then sets relevant interrupts and returns to SUSPEND mode.
8. The DMA can exit SUSPEND mode and enter the RUN state only after receiving the Transmit Poll demand in the **EMACTXPOLL** register.

**Note:** The DMA fetches the next descriptor in advance before closing the current descriptor. Therefore, the descriptor chain should have more than two different descriptors for correct and proper operation.

Figure 23-5 on page 1538 shows the flow for the TX DMA Operate-On-Second-Frame (OSF) operation.

Figure 23-5. TX DMA OSF Mode Operation Using Normal Descriptors

If using Enhanced Descriptors, TDES2 and TDES3 are replaced with TDES6 and TDES7.

### Transmit Frame Processing

The TX DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and Frame Check Sequence (FCS) fields. The Destination Address (DA), Source Address (SA), and Type/Length fields must contain valid data. If the Transmit Descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes. Frames can be data-chained and can span several buffers.

Frames must be delimited by the First Segment Descriptor and the Last Segment Descriptor, respectively. For normal descriptors, the First Descriptor bit is located at TDES1[29] and the Last Descriptor is located at TDES1[30]. For Enhanced descriptor format, the First Segment Descriptor bit is located in TDES0[28] and the Last Segment Descriptor bit is located in TDES0[29].

As transmission starts, the First Descriptor must have TDES1[29]/TDES0[28] set. When this occurs, frame data transfers from the host memory buffer to the TX FIFO. Concurrently, if the current frame has the Last Segment Descriptor (TDES1[30]/TDES0[29]) clear, the transmit process attempts to acquire the next descriptor. The transmit process expects this descriptor to have TDES1[29]/TDES0[28] clear. If TDES1[30]/TDES0[29] is clear, it indicates an intermediary buffer. If TDES1[30]/TDES0[29] is set, it indicates the last buffer of the frame. After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor word of the descriptor that has the last segment bit set in Transmit Descriptor. At this time, if Interrupt on Completion (IC) bit is set, the TI bit in the **EMACDMARIS** register is set, the next descriptor is fetched and the process repeats.

The actual frame transmission begins after the TX FIFO has reached either the transmit threshold as configured by the TTC bit field of the **EMACDMAOPMODE** register, or a full frame is contained in the TX FIFO. To wait until there is a full frame in the TX FIFO the TSF bit in the **EMACDMAOPMODE** register must be set. Descriptors are released (OWN bit in the TDES0[31] cleared) when the DMA finishes transferring the frame.

**Note:** To ensure proper transmission of a frame and the next frame, the transmit descriptor that has the Last Descriptor bit (TDES1[30]/TDES0[29]) set, must specify a non-zero buffer size.

### ***Transmit Polling Suspended***

Transmit polling can be suspended by either of the following conditions:

- The DMA detects a descriptor owned by the CPU (TDES0[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command.
- A frame transmission is aborted when a transmit error because of underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set.

If the DMA goes into SUSPEND state because of the first condition, then both the Normal Interrupt Summary (NIS) bit and the Transmit Buffer Unavailable (TU) bit are set in the **EMACDMARIS** register. If the second condition occurs, the Abnormal Interrupt Summary (AIS) bit and the Transmit Underflow (UNF) bit of the **EMACDMARIS** register are set and the information is written to Transmit Descriptor 0, causing the suspension.

In both cases, the position in the Transmit list is retained. The retained position is that of the descriptor following the last descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension case.

## **23.3.3.6 DMA Receive Operation**

The following section describes the receive operation process.

### ***Default Receive Operation***

The RX DMA engine's reception sequence is as follows:

1. The host sets up receive descriptors (RDES0-RDES3) and sets the OWN bit (RDES0[31]).
2. When the SR bit of the **EMACDMAOPMODE** register is set, the DMA enters the RUN state. While in the RUN state, the DMA polls the Receive Descriptor list, attempting to acquire free

descriptors. If the fetched descriptor is not free (is owned by the CPU), the DMA enters the Suspend state and jumps to Step 9.

3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.
5. When the buffer is full or the frame transfer is complete, the RX DMA engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to Step 7. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error (DE) bit in the RDES0 (unless flushing is disabled through the DFF bit in the **EMACDMAOPMODE** register). The DMA closes the current descriptor (clears the OWN bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value. If flushing is not disabled, then the DMA would mark it as the last descriptor. In either case, the DMA proceeds to Step 8. If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to Step 4.
7. If IEEE 1588 timestamping is enabled, the DMA writes the timestamp to the current descriptor's RDES[2] and RDES[3] (or RDES[6] and RDES[7] if using alternate descriptors). It then takes the receive frame's status and writes the status word to the current descriptor's RDES0, with the OWN bit cleared and the Last Segment (LS) bit set. If the host stopped the RX DMA by clearing the SR bit of the **EMACDMAOPMODE** register, DMA goes to the STOP state, otherwise the RX DMA proceeds to Step 8.
8. The RX DMA engine checks the last descriptor's OWN bit. If the CPU owns the descriptor (OWN bit is 0), the RU bit of the **EMACDMARIS** register is set and the DMA RX engine enters the SUSPEND state (). If the DMA owns the descriptor, the engine returns to Step 4 and awaits the next frame.
9. Before the RX DMA engine enters the SUSPEND state, partial frames are flushed from the RX FIFO. Flushing can be controlled through the DFF bit of the **EMACDMAOPMODE** register.
10. The RX DMA enters the STOP state if the CPU has cleared the SR bit of the **EMACDMAOPMODE** register. Otherwise, it exits the SUSPEND state when a Receive Poll Demand is given or the start of the next frame is available from the RX FIFO. The DMA engine proceeds to Step 2 and re-fetches the next descriptor.

The DMA does not acknowledge accepting status from the TX/RX Controller until it has completed the timestamp write-back and is ready to perform status write-back to the descriptor.

If software has enabled timestamping through the **Ethernet MAC Timestamp Control (EMACTIMSTCTRL)** register, offset 0x700, when a valid timestamp is not available for the frame (for example, because the receive FIFO was full before the timestamp could be written to it), the DMA writes all-ones to RDES2 and RDES3 (or RDES[6] and RDES[7] if using alternate descriptors). Otherwise if timestamping is not enabled, the RDES[2]/RDES[6] and RDES[3]/RDES[7] remain unchanged.

Figure 23-6 on page 1541 shows the flow of a RX DMA Operation.

Figure 23-6. RX DMA Operation Flow

If using Enhanced Descriptors, TDES2 and TDES3 are replaced with TDES6 and TDES7.

### Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- The SR bit of the **EMACDMAOPMODE** register has been set immediately after being placed in the RUN state.
- The data buffer or current descriptor is full before the frame ends for the current transfer.
- The controller has completed frame reception, but the current receive descriptor is not yet closed.
- The receive process has been suspended because of a host-owned buffer (RDES0[31]=0) and a new frame is received.
- A receive poll demand has been issued.

### ***Receive Frame Processing***

The MAC transfers the received frames to the system memory only when the frame passes the address filter and the frame size is greater than or equal to configurable threshold bytes set for the RX FIFO, or when the complete frame is written to the RX FIFO in store-and-forward mode.

If the frame fails the address filtering, it is dropped in the MAC block unless the Receive All (RA) bit is set in the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)**, offset 0x004. If the RA bit is set, then the MAC passes all received frames. Frames that are shorter than 64 bytes, because of collision or premature termination, can be removed from the RX FIFO if the DFF bit is clear in the **EMACDMAOPMODE** register.

After 64 bytes have been received, the TX/RX Controller requests the DMA block to begin transferring the frame data to the receive buffer pointed by the current descriptor. The DMA sets the First Descriptor (RDES0[9]) bit to delimit the frame after the DMA Interface becomes ready to receive a data transfer (if DMA is not fetching transmit data from the system memory). The descriptors are released when the OWN (RDES0[31]) bit is reset to 0, either as the data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both Last Descriptor (RDES0[8]) and First Descriptor (RDES0[9]) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (RDES0[8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets the RI bit of the **EMACDMARIS** register. The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host. If this occurs, the receive process sets the RU bit of the **EMACDMARIS** and enters the SUSPEND state. The position in the receive list is retained.

### ***Receive Process Suspend***

If a new receive frame arrives while the receive process is in SUSPEND state, the DMA refetches the current descriptor in the system memory. If the descriptor is now owned by the DMA, the receive process re-enters the RUN state and starts frame reception. If the descriptor is still owned by the CPU, by default, the DMA discards the current frame at the top of the RX FIFO and increments the missed frame counter. If more than one frame is stored in the RX FIFO, the process repeats. The discarding or flushing of the frame at the top of the RX FIFO can be prevented by disabling flushing through the DFF bit of the **EMACDMAOPMODE** register. In such conditions, the receive process sets the Receive Buffer Unavailable (RU) status and returns to the SUSPEND state.

## **23.3.3.7 DMA Interrupts**

Interrupts can be generated as a result of various transfer events. The current status of interrupts can be read from the **EMACDMARIS** register and are enabled to trigger an interrupt through the programming of the **Ethernet MAC DMA Interrupt Mask (EMACDMAIM)** register. There are two groups of transfer event interrupts: Normal and Abnormal. The following lists the two groups:

■ Normal Interrupts:

- Transmit Interrupt (TI, bit 0): Indicates that frame transmission is complete.
- Transmit Buffer Unavailable (TU, bit 2): Indicates the CPU owns the next descriptor in the transmit list and the DMA cannot acquire it.
- Receive Interrupt (RI, bit 6): Indicates the frame reception is complete.
- Early Receive Interrupt (ERI, bit 14): Indicates the DMA has filled the first half of the data buffer of the packet

■ Abnormal Interrupts:

- Transmit Process Stopped (TPS, bit 1): Indicates transmission is stopped.,
- Transmit Jabber Timeout (TJT, bit 3): Indicates the Transmit Jabber Timer expired.
- Receive FIFO Overflow (OVF, bit 4): Indicates the receive buffer had an overflow during frame reception.
- Transmit Underflow (UNF, bit 5): Indicates the transmit buffer had an underflow during frame transmission.
- Receive Buffer Unavailable (RU, bit): Indicates the CPU owns the next descriptor in the receive list and the DMA cannot acquire it.
- Receive Process Stopped (RPS, bit 8): Indicates the receive process entered the STOP state.
- Receive Watchdog Timeout (RWT, bit 9): Indicates a frame length greater than 2 KB is received (10,240 when Jumbo Frame is enabled)
- Early Transmit Interrupt (ETI, bit 10): Indicates a frame to be transmitted is fully transferred to the TX FIFO.
- Fatal Bus Error (FBI, bit 13): Indicates a bus error occurred.

Any of the interrupts in the Normal Interrupt group that are enabled in the **EMACDMAIM** register are ORed together to create the Normal Interrupt Summary (NIS) bit in the **EMACDMARIS** register. Any of the interrupts in the Abnormal Interrupt group that are enabled in the **EMACDMAIM** register are ORed together to create the Abnormal Interrupt Summary (AIS) bit in the **EMACDMARIS** register. Interrupts are cleared by writing a 1 to the corresponding bit position in the **EMACDMARIS** register. When all enabled interrupts within a group are cleared, the corresponding summary bit is cleared.

Interrupts are not queued and if the interrupt event occurs again before the driver has responded to it, no additional interrupts are generated. An interrupt is only generated once for simultaneous, multiple events. The driver must read the **EMACDMARIS** register for the cause of the interrupt.

The **Ethernet MAC Receive Interrupt Watchdog Timer (EMACRXINTWDT)** register, offset 0xC24 can be used to control the Receive Interrupt (RI) assertion. If the RDES1[31] bit (Receive Interrupt) bit has not been set in the receive descriptor and the **EMACRXINTWDT** register is programmed with a non-zero value, it gets activated as soon as the RX DMA completes a transfer of a received frame to system memory without asserting the receive interrupt. When this counter runs out as per the programmed value, the RI bit is set in the **EMACDMARIS** register and the interrupt is asserted

if the corresponding RI bit is enabled in the **EMACDMAIM** register. This counter gets disabled before it runs out if a frame is transferred to memory and the RI bit is set because it is enabled for that descriptor.

### 23.3.3.8 DMA Bus Error

If an internal bus error occurs during a DMA transfer, the fatal bus error (FBI) interrupt is set in the **EMACDMARIS** register and the Access Error status (AE) bit field in the **EMACDMARIS** register indicates the type of error that caused the bus error. The DMA controller can resume operation only after soft resetting the Ethernet MAC and the re-initializing the DMA.

## 23.3.4 Descriptors

The descriptor that the DMA uses is normally constructed of four words. When using the advanced timestamp feature, or source address or VLAN insertion, the enhanced descriptor should be enabled by setting the ATDS bit in the **EMACDMABUSMOD** register. This allows the descriptor to expand to eight words for storing additional information important to these enhanced features.

Figure 23-7 on page 1544 shows the normal receive and transmit descriptor configuration:

**Figure 23-7. Normal Receive and Transmit Descriptor Configuration**

### 23.3.4.1 Transmit Descriptor

The MAC requires at least one descriptor for a transmit frame. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit frame basis.

Transmit Descriptor 0 (TDES0) contains the transmitted frame status and the descriptor ownership information. Table 23-3 on page 1544 shows the information stored in TDES0.

**Table 23-3. Transmit Descriptor 0 (TDES0)**

| Bit   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | OWN: Own Bit<br>When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are empty. The ownership bit of the First Descriptor of the frame should be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit. |
| 30:18 | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table 23-3. Transmit Descriptor 0 (TDES0) (continued)**

| Bit | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17  | <p>TSS:TX Timestamp</p> <p>This status bit indicates that a timestamp has been captured for the corresponding transmit frame. When this bit is set, TDES2 and TDES3 have timestamp values that were captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES1[30]) in a descriptor is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 16  | <p>IHE: IP Header Error</p> <p>When set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when TX Checksum Offload is enabled. Otherwise, it is reserved. If the Checksum Offload Engine detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.</p>                                                                                                                                                                                                                                                                                                                                                                           |
| 15  | <p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> <li>■ TDES0[16]: IP Header Error</li> <li>■ TDES0[14]: Jabber Timeout</li> <li>■ TDES0[13]: Frame Flush</li> <li>■ TDES0[12]: Payload Checksum Error</li> <li>■ TDES0[11]: Loss of Carrier</li> <li>■ TDES0[10]: No Carrier</li> <li>■ TDES0[9]: Late Collision</li> <li>■ TDES0[8]: Excessive Collision</li> <li>■ TDES0[2]: Excessive Deferral</li> <li>■ TDES0[1]: Underflow error</li> </ul>                                                                                                                                                                                                                                      |
| 14  | <p>JT: Jabber Timeout</p> <p>When set, this bit indicates that the MAC transmitter has experienced a jabber timeout. This bit can only be set when the JD bit of the <b>EMACCFG</b> register is clear (Jabber timeout enabled).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 13  | <p>FF: Frame Flushed</p> <p>When set, this bit indicates that the DMA flushed the frame because of a software flush command given by the CPU.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 12  | <p>PCE: Payload Checksum Error</p> <p>This bit, when set, indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the IP Header's Payload Length field, or the TX/RX Controller starting to forward the frame to the MAC transmitter in the store-and-forward mode without the checksum having been calculated yet. This second error condition only occurs when the TX FIFO depth is less than the length of the Ethernet frame being transmitted and to avoid deadlock, the TX/RX Controller starts forwarding the frame when the TX FIFO is full, even in the store-and-forward mode.</p> |
| 11  | <p>LC: Loss of Carrier</p> <p>When set, this bit indicates that Loss of Carrier occurred during frame transmission. This is valid only for the frames transmitted without collision and when the MAC operates in the half-duplex mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 10  | <p>NC: No Carrier</p> <p>When set, this bit indicates that the carrier sense signal from the PHY was not asserted during transmission.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 9   | <p>LC: Late Collision</p> <p>When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times including Preamble in MII Mode). Not valid if Underflow Error (bit 1) is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 23-3. Transmit Descriptor 0 (TDES0) (continued)**

| Bit | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8   | Excessive Collision<br>When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the Disable Retry (DR) bit in <b>EMACCFG</b> register is set, this bit is set after the first collision and the transmission of the frame is aborted.                                                                                |
| 7   | VF: VLAN Frame<br>When set, this bit indicates that the transmitted frame was a VLAN-type frame.                                                                                                                                                                                                                                                                                                             |
| 6:3 | CC: Collision Count<br>This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collision bit (TDES0[8]) is set.                                                                                                                                                                                                    |
| 2   | ED: Excessive Deferral<br>When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times when Jumbo Frame is enabled). This bit is dependent on the Deferral Check (DC) bit being enabled in the <b>EMACCFG</b> register.                                                                                                           |
| 1   | UF: Underflow Error<br>When set, this bit indicates that the MAC aborted the frame because the data arrived late from system memory. Underflow Error indicates that the DMA encountered an empty Transmit Buffer while transmitting the frame. The transmission process enters the suspended state and sets both Transmit Underflow (UNF) and Transmit Interrupt (TI) bit in the <b>EMACDMARIS</b> register. |
| 0   | DB: Deferred Bit<br>When set, this bit indicates that the MAC defers before transmission because of the presence of a carrier. This bit is only valid in half-duplex mode.                                                                                                                                                                                                                                   |

TDES1 contains the buffer sizes and other bits which control the descriptor chain or ring and the frame being transferred.

**Table 23-4. Transmit Descriptor 1 (TDES1)**

| Bit | Description                                                                                                                                                                               |
|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | IC: Interrupt on Completion<br>When set this bit sets the Transmit Interrupt (TI) bit in the <b>EMACDMARIS</b> register when the frame contained in this descriptor has been transmitted. |
| 30  | LS: Last Segment<br>When set, this bit indicates that the buffer contains the last segment of the frame. When this bit is set, the TBS1 or TBS2 field should have a non-zero value.       |
| 29  | FS: First Segment<br>When set, this bit indicates that the buffer contains the first segment of a frame.                                                                                  |

**Table 23-4. Transmit Descriptor 1 (TDES1) (continued)**

| Bit   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 28:27 | <p>CIC: Checksum Insertion Control</p> <p>These bits control the insertion of checksums in Ethernet frames that encapsulate TCP, UDP, or ICMP over IPv4 or IPv6:</p> <ul style="list-style-type: none"> <li>■ 0x0: Do nothing . Checksum Engine bypassed.</li> <li>■ 0x1: Insert IPv4 header checksum. Use this value to insert IPv4 header checksum when the frame encapsulates an IPv4 datagram.</li> <li>■ 0x2: Insert TCP/UDP/ICMP checksum. The checksum is calculated over the TCP, UDP, or ICMP segment only and the TCP, UDP, or ICMP pseudo-header checksum is assumed to be present in the corresponding input frame's Checksum field. An IPv4 header checksum is also inserted if the encapsulated datagram conforms to IPv4.</li> <li>■ 0x3: Insert a TCP/UDP/ICMP checksum that is fully calculated in this engine. The TCP, UDP, or ICMP pseudo-header is included in the checksum calculation, and the input frame's corresponding Checksum field has an all-zero value. An IPv4 Header checksum is also inserted if the encapsulated datagram conforms to IPv4.</li> </ul> <p>The Checksum engine detects whether the TCP, UDP, or ICMP segment is encapsulated in IPv4 or IPv6 and processes its data accordingly.</p> |
| 26    | <p>DC: Disable CRC</p> <p>When set, the MAC does not append the Cyclic Redundancy Check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES1[29]) is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 25    | <p>TER: Transmit End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 24    | <p>TCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES1[24] is set, TBS2 (TDES1[21–11]) are don't care values. TDES1[25] takes precedence over TDES1[24].</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 23    | <p>DP: Disable Padding</p> <p>When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes and the CRC field is added despite the state of the DC (TDES1[26]) bit. This is valid only when the first segment (TDES1[29]) is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 22    | <p>TTSE: Transmit Timestamp Enable</p> <p>When set, this bit enables IEEE1588 hardware timestamping for the transmit frame referenced by the descriptor. | 10:0  | <p>TBS1: Transmit Buffer 1 Size</p> <p>These bits indicate the First Data Buffer byte size. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of TCH (Bit 24).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

TDES2 contains the address pointer to the first buffer of the descriptor.

**Table 23-5. Transmit Descriptor 2 (TDES2)**

| Bit  | Description                                                                                                                                                                                                  |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <p>Buffer 1 Address Pointer</p> <p>These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment.</p> <p><b>Note:</b> The buffer address must be in SRAM.</p> |

TDES3 contains the address pointer either to the second buffer of the descriptor or the next descriptor.

**Table 23-6. Transmit Descriptor 3 (TDES3)**

| Bit  | Description                                                                                                                                                                                                                                                                                                                                                                         |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | Buffer 2 Address Pointer (Next Descriptor Address)<br>Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the 32-bit bus when TDES1[24] is set. |

### 23.3.4.2 Receive Descriptor

The DMA requires at least two descriptors when receiving a frame. The DMA always attempts to acquire an extra descriptor in anticipation of an incoming frame. Before the DMA closes a descriptor, it attempts to acquire the next descriptor even if no frames are received. In a single descriptor (receive) system, the subsystem generates a descriptor error if the receive buffer is unable to accommodate the incoming frame and the next descriptor is not owned by the DMA.

RDES0 contains the received frame status, the frame length, and the descriptor ownership information.

**Table 23-7. Receive Descriptor 0 (RDES0)**

| Bit   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | OWN: Own Bit<br>When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.                                                                                                                                                                                                                                                          |
| 30    | AFM: Destination Address Filter Fail<br>When set, this bit indicates a frame failed in the DA filter in the MAC.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 29:16 | FL: Frame Length<br>These bits indicate the byte length of the received frame that was transferred to the system memory. This field is valid when the Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or the Overflow Error bit is clear.<br>When the Last Descriptor bit is not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. The inclusion of CRC length in the frame length depends on the settings of CRC configuration bits, ACS and CST in the <b>EMACCFG</b> register. |
| 15    | ES: Error Summary<br>Indicates the logical OR of the following bits: <ul style="list-style-type: none"> <li>■ RDES0[14]: Descriptor Error</li> <li>■ RDES0[11]: Overflow Error</li> <li>■ RDES0[7]: IPC Checksum (Type 2) or Giant Frame</li> <li>■ RDES0[6]: Late Collision</li> <li>■ RDES0[4]: Watchdog Timeout</li> <li>■ RDES0[3]: Receive Error</li> <li>■ RDES0[1]: CRC Error</li> <li>■ RDES0[0]: Payload Checksum error</li> </ul> This field is valid only when the Last Descriptor (RDES0[8]) is set.                                                          |

**Table 23-7. Receive Descriptor 0 (RDES0) (continued)**

| Bit | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14  | <p>DE: Descriptor Error</p> <p>When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.</p>                                                                                                                                                 |
| 13  | <p>SAF: Source Address Filter Fail</p> <p>When set, this bit indicates that the SA field of frame failed the SA Filter in the MAC.</p>                                                                                                                                                                                                                                                                                                                        |
| 12  | <p>LE: Length Error</p> <p>When set, this bit indicates that the actual length of the frame received and the Length/ Type field do not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset. Length error status is not valid when CRC error is present.</p>                                                                                                                                                                             |
| 11  | <p>OE: Overflow Error</p> <p>When set, this bit indicates that the received frame is damaged because of buffer overflow in RX FIFO.</p> <p><b>Note:</b> This bit is set only when the DMA transfers a partial frame to the application. This happens only when the RX FIFO is operating in the threshold mode. In the store-and-forward mode, all partial frames are dropped completely in RX FIFO.</p>                                                       |
| 10  | <p>VLAN: VLAN Tag</p> <p>When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the MAC. The VLAN tagging depends on checking VLAN fields of the received frame configured in the <b>Ethernet MAC VLAN Tag (EMACVLANTG)</b> register, offset 0x01C</p>                                                                                                                                                           |
| 9   | <p>FS: First Descriptor</p> <p>When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.</p>                                                                                                                                |
| 8   | <p>LS: Last Descriptor</p> <p>When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame.</p>                                                                                                                                                                                                                                                                                                              |
| 7   | <p>IPC Checksum Error or Giant Frame</p> <p>When set, this bit indicates an error in the IPv4 or IPv6 header. This error can be because of inconsistent Ethernet Type field and IP header Version field values, a header checksum mismatch in IPv4, or an Ethernet frame lacking the expected number of IP header bytes.</p>                                                                                                                                  |
| 6   | <p>LC: Late Collision</p> <p>When set, this bit indicates that a late collision has occurred while receiving the frame in half-duplex mode.</p>                                                                                                                                                                                                                                                                                                               |
| 5   | <p>FT: Frame Type</p> <p>When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 1,536). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames which are less than 14 bytes. In addition when the IPC bit is set in the <b>EMACCFG</b> register, this bit conveys different information. See Table 23-8 on page 1550.</p> |
| 4   | <p>RWT: Receive Watchdog Timeout</p> <p>When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.</p>                                                                                                                                                                                                                                         |
| 3   | <p>RE: Receive Error</p> <p>When set, this bit indicates that an error occurred during frame reception.</p>                                                                                                                                                                                                                                                                                                                                                   |
| 2   | <p>DE: Dribble Bit Error</p> <p>When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode.</p>                                                                                                                                                                                                                                                                               |
| 1   | <p>CE: CRC Error</p> <p>When set this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8]) is set..</p>                                                                                                                                                                                                                                                      |

**Table 23-7. Receive Descriptor 0 (RDES0) (continued)**

| Bit | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | <p>RX MAC Address or Payload Checksum Error</p> <p>When set, this bit indicates that the <b>Ethernet MAC Address n (EMACADDRXH/L)</b> registers value matched the frame's DA field. When reset, this bit indicates that the <b>Ethernet MAC Address 0 H/L (EMACADDR0H/L)</b> register value matched the DA field. This bit is invalid when Bit 30 is set.</p> <p>If the Full Checksum Offload Engine is enabled, this bit, when set, indicates that the received number of payload bytes does not match the value indicated in the Length field of the encapsulated IPv4 or IPv6 datagram in the received Ethernet frame</p> |

Table Table 23-8 on page 1550 shows the frame information conveyed in bits 7, 5, and 0 of RDES0 when the Checksum Offload Engine is enabled and disabled through the IPC bit in the **EMACCFG** register.

**Table 23-8. RDES0 Checksum Offload bits**

| Bit 5: Frame Type | Bit 7: IPC Checksum Error | Bit 0: Payload Checksum Error | IPC bit value in EMACCFG register | Frame Status                                                                                                                                      |
|-------------------|---------------------------|-------------------------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                 | 0                         | 0                             | X                                 | IEEE 802.3 Type frame (Length field value is less than 1,536). This status definition is valid even when the Checksum Offload engine is disabled. |
| 1                 | 0                         | 0                             | 0                                 | IPv4/IPv6 Type frame in which no checksum error is detected.                                                                                      |
| 1                 | 0                         | 0                             | 1                                 | The frame is an IEEE 802.3 Type frame (Length field value is greater than or equal to 1,536).                                                     |
| 1                 | 0                         | 1                             | 1                                 | IPv4/IPv6 Type frame with a payload checksum error detected                                                                                       |
| 1                 | 1                         | 1                             | 1                                 | IPv4/IPv6 Type frame with both IP header and payload checksum errors detected                                                                     |
| 0                 | 0                         | 1                             | 1                                 | IPv4/IPv6 Type frame with no IP header checksum error and the payload check bypassed, due to an unsupported payload                               |
| 0                 | 1                         | 1                             | 1                                 | A Type frame that is neither IPv4 or IPv6 (the Checksum Offload engine bypasses checksum completely.)                                             |
| 0                 | 1                         | 0                             | X                                 | Reserved                                                                                                                                          |

RDES1 contains the buffer sizes and other bits that control the descriptor chain or ring.

**Table 23-9. Receive Descriptor 1 (RDES1)**

| Bit   | Description                                                                                                                                                                                                                                                                                         |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <p>Disable Interrupt on Completion</p> <p>When set this bit prevents the setting of the bit Receive Interrupt (RI) bit in the <b>EMACDMARIS</b> register and prevents the receive interrupt from being asserted.</p>                                                                                |
| 30:26 | Reserved                                                                                                                                                                                                                                                                                            |
| 25    | <p>RER: Receive End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a Descriptor Ring.</p>                                                                                             |
| 24    | <p>RCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When RDES1[24] is set, RBS2 (RDES1[21-11]) is a don't care value. RDES1[25] takes precedence over RDES1[24].</p> |
| 23:22 | Reserved                                                                                                                                                                                                                                                                                            |

**Table 23-9. Receive Descriptor 1 (RDES1) (continued)**

| Bit   | Description                                                                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 21:11 | RBS2: Receive Buffer 2 Size<br>These bits indicate the Second Data Buffer in bytes. This field is not valid if RDES1[24] is set.                                                                                 |
| 10:0  | RBS1: Receive Buffer 1 Size<br>These bits indicate the First Data Buffer byte size. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 24). |

RDES2 contains the address pointer to the first data buffer in the descriptor.

**Table 23-10. Receive Descriptor 2 (RDES2)**

| Bit  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | Buffer 1 Address Pointer<br>These bits indicate the physical address of Buffer 1. The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of the frame. The DMA performs a write operation with the RDES2[3:0, 2:0, or 1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3:0, 2:0, or 1:0], corresponding to bus width of 128, 64, or 32, if the address pointer is to a buffer where the middle or last part of the frame is stored. |

**Table 23-11. Receive Descriptor 3 (RDES3)**

| Bit  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | Buffer 2 Address Pointer (Next Descriptor Address)<br>These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[24] is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[1:0] = 0, corresponding to a bus width of 32.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[1:0], if the address pointer is to a buffer where the middle or last part of the frame is stored. |

### 23.3.4.3 IEEE 1588-2005 Timestamp Descriptor Format

If the IEEE 1588-2005 timestamp feature is enabled, the DES2 and DES3 descriptor fields take on a different meaning when the DMA closes the descriptor. The DMA updates the DES2 and DES3 with the timestamp value in these two descriptor fields before clearing the OWN bit in DES0. When the IEEE 1588-2005 timestamping is enabled, the DES2 and DES3 fields are updated with the timestamp value. DES2 is updated with the sub-second field (also called Timestamp Low (TSL)) value and the DES3 field is updated with the seconds field (also called Timestamp High (TSH)).

The TDES2 and TDES3 field descriptions for timestamping enabled are shown in Table 23-12 on page 1551 and Table 23-13 on page 1552. In addition, bit 17 of the TDES0 descriptor and bit 22 of the TDES1 descriptor are valid during timestamping.

**Table 23-12. Transmit Descriptor 2 (TDES2) with 1588-2005 Timestamping Enabled**

| Bit  | Description                                                                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | TTSL: Transmit Frame Timestamp Low<br>This field is updated by DMA with the least significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment control bit (LS) in the descriptor is set. |

**Table 23-13. Transmit Descriptor 3 (TDES3) with 1588-2005 Timestamping Enabled**

| Bit  | Description                                                                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | TTSH: Transmit Frame Timestamp High<br>This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment control bit (LS) in the descriptor is set. |

The RDES2 and RDES3 field descriptions for timestamping enabled are shown in Table 23-14 on page 1552 and Table 23-15 on page 1552. Note that when the timestamp feature is disabled, the DMA does not update the RDES2 and RDES2 fields of the descriptor before closing RDES0.

**Table 23-14. Receive Descriptor 2 (RDES2) with 1588-2005 Timestamping Enabled**

| Bit  | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | RTSL: Receive Frame Timestamp Low<br>The DMA updates this field with the least significant 32 bits of the timestamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8]). When this field and the RTSH field in RDES3 show an all-ones value, the timestamp must be treated as corrupt. |

**Table 23-15. Receive Descriptor 3 (RDES3) with 1588-2005 Timestamping Enabled**

| Bit  | Description                                                                                                                                                                                                                                                                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | RTSH: Receive Frame Timestamp High<br>The DMA updates this field with the most significant 32 bits of the timestamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8]). When this field and RDES2's RTSL field show all-ones values, the timestamp must be treated as corrupt. |

#### 23.3.4.4 Enhanced Descriptors

When the IEEE 1588-2008 Advanced Timestamp feature or the SA, VLAN or CRC Insertion feature is enabled, the descriptor structure is eight words instead of four words. If enhanced descriptors are used, then the DES6 and DES7 fields for receive and transmit contain the timestamp high and low data. In addition, the control and status bits in DES0 and DES1 are changed.

##### **Enhanced Transmit Descriptor**

Figure 23-8 on page 1553 shows the enhanced transmit descriptor. Software must program the control bits TDES0[31:18] during descriptor initialization. When the DMA updates the descriptor, it writes back all the control bits to their initialized value, clears the OWN bit and updates the status bits.

With advanced timestamp support, the snapshot of the timestamp to be taken can be enabled for a given frame by setting Bit 25 (TTSE) of TDES0. When the descriptor is closed (that is, when the OWN bit is cleared), the timestamp is written into TDES6 and TDES7.

**Note:** When Advanced Timestamp feature is enabled, software should set the ATDS bit of the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)** register, offset 0xC00, so that the DMA operates with extended descriptor size. When this control bit is reset, the TDES4-TDES7 descriptor space is not valid.

**Figure 23-8. Enhanced Transmit Descriptor Structure**

|       | 31                                                    | 23                         | 15               | 7            | 0                |                            |                       |              |
|-------|-------------------------------------------------------|----------------------------|------------------|--------------|------------------|----------------------------|-----------------------|--------------|

| TDES1 | CTRL [31:29]                                          | Byte Count Buffer2 [28:16] |                  |              | Reserved         | Byte Count Buffer 1 [12:0] |                       |              |
| TDES2 | Buffer1 Address [31:0]                                |                            |                  |              |                  |                            |                       |              |
| TDES3 | Buffer2 Address [31:0]/Next Descriptor Address [31:0] |                            |                  |              |                  |                            |                       |              |
| TDES4 | Reserved                                              |                            |                  |              |                  |                            |                       |              |
| TDES5 | Reserved                                              |                            |                  |              |                  |                            |                       |              |
| TDES6 | Transmit Timestamp Low [31:0]                         |                            |                  |              |                  |                            |                       |              |
| TDES7 | Transmit Timestamp High [31:0]                        |                            |                  |              |                  |                            |                       |              |

The following tables define the Enhanced Transmit Descriptors.

**Table 23-16. Enhanced Transmit Descriptor 0 (TDES0)**

| Bit | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | OWN: Own Bit<br>When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are empty. The ownership bit of the First Descriptor of the frame should be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit. |
| 30  | IC: Interrupt on Completion<br>When set, this bit sets the Transmit Interrupt (Register 5[0]) after the present frame has been transmitted.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 29  | LS: Last Segment<br>When set, this bit indicates that the buffer contains the last segment of the frame. When this bit is set, the TBS1 or TBS2 field in TDES1 should have a non-zero value.                                                                                                                                                                                                                                                                                                                                                                          |
| 28  | FS: First Segment<br>When set, this bit indicates that the buffer contains the first segment of a frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table 23-16. Enhanced Transmit Descriptor 0 (TDES0) (continued)**

| Bit   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 27    | <p>DC: Disable CRC</p> <p>When this bit is set, the MAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES0[28]) is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 26    | <p>DP: Disable Pad</p> <p>When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This is valid only when the first segment (TDES0[28]) is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 25    | <p>TTSE: Transmit Timestamp Enable</p> <p>This status bit indicates that a timestamp has been captured for the corresponding transmit frame. When set, this bit enables IEEE1588 hardware timestamping for the transmit frame referenced by the descriptor. This bit is only valid when the First Segment Control bit (TDES0[28]) is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 24    | <p>CRCR: CRC Replacement Control</p> <p>When set, the MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The CPU should ensure that the CRC bytes are present in the frame being transferred from the Transmit Buffer. CRC replacement is done only when Bit 27 (DC) is set to 1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 23:22 | <p>CIC: Checksum Insertion Control</p> <p>These bits control the checksum calculation and insertion. The following list describes the bit encoding:</p> <ul style="list-style-type: none"> <li>■ 0x0= Checksum Insertion Disabled</li> <li>■ 0x1= Only IP header checksum calculation and insertion are enabled.</li> <li>■ 0x2=IP header checksum and payload checksum calculation and insertion are enabled, but pseudoheader checksum is not calculated in hardware.</li> <li>■ 0x3= IP Header checksum and payload checksum calculation and insertion are enabled, and pseudoheader checksum is calculated in hardware.</li> </ul> <p>This field is valid when the First Segment control bit (TDES0[28]) is set.</p>                                                                                                              |
| 21    | <p>TER: Transmit End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 20    | <p>TCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a "don't care" value. TDES0[21] takes precedence over TDES0[20].</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 19:18 | <p>VLIC: VLAN Insertion Control</p> <p>When set, these bits request the MAC to perform VLAN tagging or untagging before transmitting the frames. If the frame is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes.</p> <p>The values of this field are as follows:</p> <ul style="list-style-type: none"> <li>■ 0x0= Do not add a VLAN tag</li> <li>■ 0x1= Remove the VLAN tag from the frames before transmission.</li> <li>■ 0x2= Insert a VLAN tag with the tag value programmed in the <b>Ethernet MAC VLAN Tag Inclusion or Replacement (EMACVLNINCREP)</b> register, offset 0x584.</li> <li>■ 0x3= Replace the VLAN tag in frame with the tag value programmed in the <b>EMACVLNINCREP</b> register. This field is valid when the First Segment control bit (TDES0[28]) is set.</li> </ul> |
| 17    | <p>TTSS:TX Timestamp</p> <p>This status bit indicates that a timestamp has been captured for the corresponding transmit frame. When this bit is set, TDES6 and TDES7 have timestamp values that were captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES0[29]) in a descriptor is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table 23-16. Enhanced Transmit Descriptor 0 (TDES0) (continued)**

| Bit | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16  | <p>IHE: IP Header Error</p> <p>When set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when TX Checksum Offload is enabled. Otherwise, it is reserved. If the Checksum Offload Engine detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.</p>                                                                                                                                      |
| 15  | <p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> <li>■ TDES0[16]: IP Header Error</li> <li>■ TDES0[14]: Jabber Timeout</li> <li>■ TDES0[13]: Frame Flush</li> <li>■ TDES0[12]: Payload Checksum Error</li> <li>■ TDES0[11]: Loss of Carrier</li> <li>■ TDES0[10]: No Carrier</li> <li>■ TDES0[9]: Late Collision</li> <li>■ TDES0[8]: Excessive Collision</li> <li>■ TDES0[2]: Excessive Deferral</li> <li>■ TDES0[1]: Underflow error</li> </ul> |
| 14  | <p>JT: Jabber Timeout</p> <p>When set, this bit indicates that the MAC transmitter has experienced a jabber timeout. This bit can only be set when the Jabber Disabled (JD) bit of the <b>EMACCFG</b> register is clear.</p>                                                                                                                                                                                                                                                                                        |
| 13  | <p>FF: Frame Flushed</p> <p>When set, this bit indicates that the DMA flushed the frame because of a software flush command given by the CPU.</p>                                                                                                                                                                                                                                                                                                                                                                   |
| 12  | <p>IPE: IP Payload Error</p> <p>When set, this bit indicates that MAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch.</p>                                                                                                                                     |
| 11  | <p>LC: Loss of Carrier</p> <p>When set, this bit indicates that Loss of Carrier occurred during frame transmission. This is valid only for the frames transmitted without collision and when the MAC operates in half-duplex mode.</p>                                                                                                                                                                                                                                                                              |
| 10  | <p>NC: No Carrier</p> <p>When set, this bit indicates that the carrier sense signal from the PHY was not asserted during transmission.</p>                                                                                                                                                                                                                                                                                                                                                                          |
| 9   | <p>LC: Late Collision</p> <p>When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times including Preamble in MII Mode). Not valid if Underflow Error (bit 1) is set.</p>                                                                                                                                                                                                                                                              |
| 8   | <p>Excessive Collision</p> <p>When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the Disable Retry (DR) bit in <b>EMACCFG</b> register is set, this bit is set after the first collision and the transmission of the frame is aborted.</p>                                                                                                                                                                            |
| 7   | <p>VF: VLAN Frame</p> <p>When set, this bit indicates that the transmitted frame was a VLAN-type frame.</p>                                                                                                                                                                                                                                                                                                                                                                                                         |
| 6:3 | <p>CC: Collision Count</p> <p>This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collision bit (TDES0[8]) is set.</p>                                                                                                                                                                                                                                                                                                |

**Table 23-16. Enhanced Transmit Descriptor 0 (TDES0) (continued)**

| Bit | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | ED: Excessive Deferral<br>When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times when Jumbo Frame is enabled). This bit is dependent on the Deferral Check (DC) bit being enabled in the <b>EMACCFG</b> register.                                                                                                           |
| 1   | UF: Underflow Error<br>When set, this bit indicates that the MAC aborted the frame because the data arrived late from system memory. Underflow Error indicates that the DMA encountered an empty Transmit Buffer while transmitting the frame. The transmission process enters the suspended state and sets both Transmit Underflow (UNF) and Transmit Interrupt (TI) bit in the <b>EMACDMARIS</b> register. |
| 0   | DB: Deferred Bit<br>This bit indicates the deferral mechanism is active and that the transmit state machine sends a JAM pattern to defer reception when it senses a carrier before a normal transmission is scheduled.                                                                                                                                                                                       |

**Table 23-17. Enhanced Transmit Descriptor 1 (TDES1)**

| Bit   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:29 | SAIC: SA Insertion Control<br>These bits request the MAC to add or replace the Source Address field in the Ethernet frame with the value given in the MAC Address 0 register. If the Source Address field is modified in a frame, the MAC automatically recalculates and replaces the CRC bytes.<br>The Bit 31 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[30:29]:<br><ul style="list-style-type: none"> <li>■ 0x0= Do not include the source address.</li> <li>■ 0x1= Insert the source address. For reliable transmission, the application must provide frames without source addresses.</li> <li>■ 0x2= Replace the source address. For reliable transmission, the application must provide frames with source addresses.</li> <li>■ 0x3= Reserved</li> </ul> These bits are valid when the First Segment control bit (TDES0[28]) is set. |
| 28:16 | TBS2: Transmit Buffer 2 Size<br>This field indicates the second data buffer size in bytes. This field is not valid if TDES0[20] is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 15:13 | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 12:0  | TBS1: Transmit Buffer 1 Size<br>These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 23-18. Enhanced Transmit Descriptor 2 (TDES2)**

| Bit  | Description                                                                                                                                                                         |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | Buffer 1 Address Pointer<br>These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. Note that the buffers are stored in SRAM. |

**Table 23-19. Enhanced Transmit Descriptor 3 (TDES3)**

| Bit  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <p>Buffer 2 Address Pointer (Next Descriptor Address)</p> <p>Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES0[20]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES0[20] is set.</p> <p>Note that the buffers are stored in SRAM.</p> |

**Table 23-20. Enhanced Transmit Descriptor 6 (TDES6)**

| Bit  | Description                                                                                                                                                                                                                                                                                                                              |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <p>TTSL: Transmit Frame Timestamp Low</p> <p>This field is updated by DMA with the least significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment bit (LS), TDES0[29], in the descriptor is set and Timestamp status (TTSS) bit, TDES0[17], is set.</p> |

**Table 23-21. Enhanced Transmit Descriptor 7 (TDES7)**

| Bit  | Description                                                                                                                                                                                                                                                                                                                             |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <p>TTSH: Transmit Frame Timestamp High</p> <p>This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding receive frame. This field has the timestamp only if the Last Segment bit (LS), TDES0[29], in the descriptor is set and Timestamp status (TTSS) bit, TDES0[17], is set.</p> |

**Enhanced Receive Descriptor**

Figure 23-9 on page 1558 shows the enhanced receive descriptor. This descriptor is used when Advanced Timestamp or the Checksum Offload Engine is enabled.

**Note:** When Advanced Timestamp feature is enabled, software should set the ATDS bit of the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)** register, offset 0xC00, so that the DMA operates with extended descriptor size. When this bit is clear, the RDES4-RDES7 descriptor space is not valid.

**Figure 23-9. Enhanced Receive Descriptor Structure**

The following tables define the Enhanced Receive Descriptors.

**Table 23-22. Enhanced Receive Descriptor 0 (RDES0)**

| Bit   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | OWN: Own Bit<br>When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.                                                                                                                                                                                                                                                                      |
| 30    | AFM: Destination Address Filter Fail<br>When set, this bit indicates a frame failed in the DA filter in the MAC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 29:16 | FL: Frame Length<br>These bits indicate the byte length of the received frame that was transferred to the system memory. This field is valid when the Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or the Overflow Error bit (RDES0[11]) is clear.<br>When the Last Descriptor bit is not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. The inclusion of CRC length in the frame length depends on the settings of CRC configuration bits, ACS and CST in the <b>EMACCFG</b> register. |

**Table 23-22. Enhanced Receive Descriptor 0 (RDES0) (continued)**

| Bit | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | <p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> <li>■ RDES0[14]: Descriptor Error</li> <li>■ RDES0[11]: Overflow Error</li> <li>■ RDES0[7]: Giant Frame</li> <li>■ RDES0[6]: Late Collision</li> <li>■ RDES0[4]: Watchdog Timeout</li> <li>■ RDES0[3]: Receive Error</li> <li>■ RDES0[1]: CRC Error</li> <li>■ RDES[4:3]: IP Header or Payload Error</li> </ul> <p>This field is valid only when the Last Descriptor (RDES0[8]) is set.</p>                                                                                   |
| 14  | <p>DE: Descriptor Error</p> <p>When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.</p>                                                                                                                                                                                                                                                                                    |
| 13  | <p>SAF: Source Address Filter Fail</p> <p>When set, this bit indicates that the SA field of frame failed the SA Filter in the MAC.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 12  | <p>LE: Length Error</p> <p>When set, this bit indicates that the actual length of the frame received and the Length/ Type field do not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset. Length error status is not valid when CRC error is present.</p>                                                                                                                                                                                                                                                                                                                |
| 11  | <p>OE: Overflow Error</p> <p>When set, this bit indicates that the received frame is damaged because of buffer overflow in RX FIFO.</p> <p><b>Note:</b> This bit is set only when the DMA transfers a partial frame to the application. This happens only when the RX FIFO is operating in the threshold mode. In the store-and-forward mode, all partial frames are dropped completely in RX FIFO.</p>                                                                                                                                                                                          |
| 10  | <p>VLAN: VLAN Tag</p> <p>When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the MAC. The VLAN tagging depends on checking VLAN fields of the received frame configured in the <b>Ethernet MAC VLAN Tag (EMACVLANTG)</b> register, offset 0x01C</p>                                                                                                                                                                                                                                                                                              |
| 9   | <p>FS: First Descriptor</p> <p>When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.</p>                                                                                                                                                                                                                                                                   |
| 8   | <p>LS: Last Descriptor</p> <p>When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7   | <p>Timestamp Available or Giant Frame</p> <p>When Advanced Timestamp feature is enabled, this bit indicates that a snapshot of the Timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This is valid only when the Last Descriptor bit (RDES0[8]) is set.</p> <p>Otherwise, this bit, when set, indicates the Giant Frame Status. Giant frames are larger than 1,518-byte (or 1,522-byte for VLAN or 2,000-byte when Bit 27 of MAC Configuration register is set) normal frames and larger than 9,018-byte (9,022-byte for VLAN) frame when Jumbo Frame processing is enabled.</p> |
| 6   | <p>LC: Late Collision</p> <p>When set, this bit indicates that a late collision has occurred while receiving the frame in half-duplex mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 23-22. Enhanced Receive Descriptor 0 (RDES0) (continued)**

| Bit | Description                                                                                                                                                                                                                                                                                                 |
|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | <p>FT: Frame Type</p> <p>When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 1,536). When this bit is reset, it indicates that the received frame is an IEEE 802.3 frame. This bit is not valid for Runt frames less than 14 bytes.</p> |
| 4   | <p>RWT: Receive Watchdog Timeout</p> <p>When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.</p>                                                                                       |
| 3   | <p>RE: Receive Error</p> <p>When set, this bit indicates that an error occurred during frame reception.</p>                                                                                                                                                                                                 |
| 2   | <p>DE: Dribble Bit Error</p> <p>When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode.</p>                                                                                                                             |
| 1   | <p>CE: CRC Error</p> <p>When set this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor bit (RDES0[8]) is set.</p>                                                                                                 |
| 0   | <p>Extended Status Available/RX MAC Address</p> <p>This bit, when set, indicates that the extended status is available in descriptor word 4 (RDES4). This is valid only when the Last Descriptor bit (RDES0[8]) is set. This bit is invalid when Bit 30 is set.</p>                                         |

**Table 23-23. Enhanced Receive Descriptor 1 (RDES1)**

| Bit   | Description                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <p>Disable Interrupt on Completion</p> <p>When set this bit prevents the setting of the bit Receive Interrupt (RI) bit in the <b>EMACDMARIS</b> register and prevents the receive interrupt from being asserted.</p>                                                                                                                                                                                                      |
| 30:29 | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 28:16 | <p>RBS2: Receive Buffer 2 Size</p> <p>These bits indicate the second data buffer size. The buffer size must be a multiple of 4, even if the value of RDES3 (buffer2 address pointer) is not aligned to the bus width. If the buffer size is not an appropriate multiple of 4, the resulting behavior is undefined. This field is not valid if RCH bit (RDES1[14]) is set.</p>                                             |
| 15    | <p>RER: Receive End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a Descriptor Ring.</p>                                                                                                                                                                                                                   |
| 14    | <p>RCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a don't care value. RDES1[15] takes precedence over RDES1[14].</p>                                                                                                                        |
| 13    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 12:0  | <p>RBS1: Receive Buffer 1 Size</p> <p>Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4 even if the value of RDES2 (buffer 1 address pointer) is not aligned. When the buffer size is not a multiple of 4, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor depending on the value of RCH (Bit 14).</p> |

**Table 23-24. Enhanced Receive Descriptor 2 (RDES2)**

| Bit  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <p>Buffer 1 Address Pointer</p> <p>These bits indicate the physical address of Buffer 1. The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. The DMA performs a write operation with the RDES2[1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored.</p> <p>Note that buffers should be word-aligned.</p> |

**Table 23-25. Enhanced Receive Descriptor 3 (RDES3)**

| Bit  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <p>Buffer 2 Address Pointer (Next Descriptor Address)</p> <p>These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[14]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[14] is set, the buffer (Next Descriptor) address pointer must be bus word-aligned (RDES3[1:0] = 0). However, when RDES1[14] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3 [1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored.</p> |

The availability of the extended status is indicated by Bit 0 of RDES0. The following descriptors are available only when the Advanced Timestamp or IP Checksum Full Offload feature is enabled.

**Table 23-26. Enhanced Received Descriptor 4 (RDES4)**

| Bit   | Description                                                                                                                                                                                                                                                                                                        |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:15 | Reserved                                                                                                                                                                                                                                                                                                           |
| 14    | <p>Timestamp Dropped</p> <p>When set, this bit indicates that the timestamp was captured for this frame but got dropped in the RX FIFO because of overflow.</p>                                                                                                                                                    |
| 13    | <p>PTP Version</p> <p>When set, this bit indicates that the received PTP message uses the IEEE 1588 version 2 format. When reset, it uses the version 1 format.</p>                                                                                                                                                |
| 12    | <p>PTP Frame Type</p> <p>When set, this bit indicates that the PTP message is sent directly over Ethernet. When this bit is clear and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information about IPv4 or IPv6 can be obtained from Bits 6 and 7.</p> |

**Table 23-26. Enhanced Received Descriptor 4 (RDES4) (continued)**

| Bit  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11:8 | <p>MessageType</p> <p>These bits are encoded to give the type of the message received:</p> <ul style="list-style-type: none"> <li>■ 0x0= No PTP message received</li> <li>■ 0x1= SYNC (all clock types)</li> <li>■ 0x2= Follow_Up (all clock types)</li> <li>■ 0x3= Delay_Req (all clock types)</li> <li>■ 0x4= Delay_Resp (all clock types)</li> <li>■ 0x5= Pdelay_Req (in peer-to-peer transparent clock)</li> <li>■ 0x6= Pdelay_Resp (in peer-to-peer transparent clock)</li> <li>■ 0x7= Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock)</li> <li>■ 0x8= Announce</li> <li>■ 0x9= Management</li> <li>■ 0xA= Signaling</li> <li>■ 0xB to 0xE= Reserved</li> <li>■ 0xF= PTP packet with Reserved message type</li> </ul> |

This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).</p> |

### 23.3.5 TX/RX Controller

The TX/RX Controller consists of a FIFO memory which buffers and regulates the frames between the system memory and the MAC. It also controls the data transferred between clock domains. Both the transmit and receive data paths are 32-bits wide. The TX FIFO and RX FIFO are each 2 KB in depth.

At reset, the TX/RX Controller is configured and ready to manage data flow to and from the DMA to the MAC. Note that the DMA and MAC must be initialized by the application out of reset.

#### 23.3.5.1 Transmit (TX) Control Path

The DMA controller is used for all Ethernet transmissions. The Ethernet frames are read from memory and transferred to the TX FIFO by the DMA. When the MAC is available, the frame is transferred from the FIFO. When the end-of-frame (EOF) is transferred, the MAC notifies the DMA the status of the transmission.

The TX FIFO has a depth of 2 KB. The FIFO fill level has the capability of triggering the DMA to initiate a burst transfer. The DMA also transfers start-of-frame (SOF), end-of-frame (EOF), CRC and pad-insertion information to the TX/RX Controller so that this information can be passed to the MAC when it is ready for transmission from the TX FIFO.

Data can be transmitted to the MAC in threshold mode or store-and-forward mode. If the TTC field is configured in the **Ethernet MAC DMA Operation Mode (EMACDMAOPMODE)** register at offset 0xC18 and the TSF bit in the same register is 0x0, then the TX Controller is operating in threshold mode. In this mode, the data is transferred to the MAC when the number of bytes in the FIFO crossed the value configured in the TTC bit field or when the end-of-frame is written before the threshold is crossed. In store-and forward mode, the TTC bit field is configured and the TSF bit is set. Data is transferred to the MAC only when one or more of the following conditions are true:

- A complete frame is stored in the FIFO
- The TX FIFO does not have space to accommodate the requested burst length

With these conditions, the TX Controller continues store-and-forward mode even if the Ethernet frame length is bigger than the TX FIFO size.

The TX FIFO can be flushed of all contents by setting the FTF bit in the **EMACDMAOPMODE** register. This bit is self-clearing and initializes the FIFO pointers to the default state. If the FTF bit is set during a frame transfer from the TX Controller to the MAC, then the TX Controller stops further transfer. Early termination of the transfer causes a underflow event and this status is communicated to the DMA.

### ***Transmit Operation***

During a transmit, single-packet or double-packets can reside in the buffer. The following describes the details of each:

- Single-packet transmit: During single packet transmission, the DMA controller fetches data from the CPU memory and forwards it to the TX FIFO and continues to receive data until the end-of-frame is transferred. The data is transmitted from the TX FIFO to the MAC by the TX/RX Controller when the threshold level is crossed or a full packet of data is received into the TX FIFO. When the TX/RX Controller receives acknowledgment from the MAC that it has received the EOF, it notifies the DMA so another transmit can begin.
- Two-packet transmit: Because the DMA must update the descriptor status before releasing it to the CPU, there can be at most two frames inside a transmit FIFO. The second frame is fetched by the DMA and put into the TX FIFO only if the OSF bit is set in the **EMACDMAOPMODE** register at offset 0xC18. If this bit is not set, the next frame is fetched from memory only after the MAC has completely processed the frame and the DMA has released the descriptors.

If the OSF bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to be updated. The TX/RX Controller receives the second frame into the FIFO while transmitting the first frame. As soon as the first frame has been transferred and the status is received from the MAC, the TX/RX Controller sends the acknowledgement to the DMA. If the DMA has already completed sending the second packet to the TX/RX Controller, it must wait for the status of the first packet before proceeding to the next frame.

### ***Collision and Retransmission***

If a collision occurs at the MAC application interface while the TX/RX Controller is transferring data to the MAC, the transmission is aborted and the MAC indicates a retry attempt by giving a collision status before the EOF is transferred to the TX/RX Controller from the DMA. This enables the TX/RX Controller to retry transmission of the frame data from the FIFO.

After more than 96 bytes are transferred to the MAC, the FIFO controller clears space in the FIFO and makes it available to the DMA to transfer more data. Retransmission is not possible after this threshold is crossed or when the MAC indicates a late collision event.

When a frame transmission is aborted because of underflow and a collision event follows, which initiates a retry, then the retry has higher priority than the abort.

#### ***TX FIFO Flush Operation***

The TX FIFO can be flushed by setting the FTF bit in the **EMACDMAOPMODE** register. The flush operation is immediate and the TX/RX Controller clears the TX FIFO and the corresponding pointers to the initial state even if it is in the middle of transferring a frame to the MAC. The data which is already accepted by the MAC transmitter is not flushed. This data is scheduled for transmission and results in an underflow event because the TX FIFO did not complete the transfer or the rest of the frame. As in all underflow conditions, a runt frame is transmitted and observed on the line. The status of such a frame is marked with both underflow and frame flush events in the Transmit Descriptor 0 (TDES0) word.

The TX/RX Controller also stops accepting any data from the DMA during the flush operation. It generates and transfers Transmit Status Words to the application for the frames that are flushed inside the FIFO, including partial frames. Frames that are completely flushed in the TX/RX Controller are identified by setting the Flush Status (FF) bit in the Transmit Descriptor 0 (TDES0) word. The TX/RX Controller completes the flush operation when the DMA accepts all of the status words for the frames that were flushed and then clears the TX FIFO Flush control (FTF) bit in the **EMACDMAOPMODE** register. At this point, the TX/RX Controller starts accepting new frames from the DMA.

#### ***Transmit Status Word***

At the end of the transfer of the Ethernet frame to the MAC and after the MAC completes the transmission of the frame, the TX/RX delivers a transmit status word (TDES0) to the application. If IEEE timestamping is enabled, the TX/RX Controller returns the specific frame's 64-bit timestamp, along with the transmit status word. The fields for the Transmit Descriptors are described in "Descriptors" on page 1544.

### **23.3.5.2 Receive (RX) Control Path**

TX/RX Controller receives frames from the MAC and pushes them into the RX FIFO. When the fill level of the RX FIFO crosses the programmed RX Threshold, the DMA is notified.

#### ***Receive Operation***

During a receive operation the TX/RX Controller is a slave to the MAC. The steps of the receive operation are as follows:

1. The MAC receives a frame. This data, along with SOF, EOF and byte enable information is sent to the TX/RX Controller. The TX/RX Controller accepts the data and pushes it into the RX FIFO. After the EOF is transferred, the MAC drives the status word, which is also pushed in to the RX FIFO.
2. When timestamp is enabled by setting the TSEN bit in the **Ethernet MAC Timestamp Control (EMACTIMSTCTRL)** register, at offset 0x700, and the 64-bit timestamp is present with the receive status, it is appended to the frame and received by the MAC and pushed into the TX FIFO before the corresponding receive status word is written. Thus, two additional locations per frame are taken for storing timestamp in the RX FIFO.

3. Data can be sent to the TX/RX Controller in cut-through mode or store-and-forward mode. When the RTC bit field of the **EMACDMAOPMODE** register is set to 0x0 and cut-through mode is enabled (RSF=0), the TX/RX Controller indicates availability to transfer to the DMA when 64 bytes are in the RX FIFO or a full packet of data has been received into the RX FIFO. When the DMA initiates transfers to system memory, the TX/RX Controller continues to transfer data from the RX FIFO until a complete packet has been transferred. When EOF has occurred, the TX/RX Controller sends the status word to the DMA.

**Note:** The timestamp transfer takes two clock cycles and the lower 32-bits of the timestamp are sent first when timestamping is enabled.

When the RSF bit is set in the **EMACDMAOPMODE** register, RX FIFO store-and-forward mode is enabled and a frame is read by the DMA only after it is completely written into the RX FIFO. In this mode, only valid frames are read and forwarded to the application. In cut-through mode, some error frames are not dropped because the error status is received at the end of the frame and by that time the start of that frame has already been read out of the RX FIFO.

The TX/RX Controller is capable of storing any number of frames in the RX FIFO as long as it is not full.

### **Error Handling**

If the RX FIFO is full before it receives the EOF data from the MAC, an overflow is declared, the entire frame (including the status word) is dropped and the **Ethernet MAC Missed Frame and Buffer Overflow Counter (EMACMFBOP)** register is incremented. These error actions occur even if the FEF bit is set in the **EMACDMAOPMODE** register. If the start address of such a frame has already been transferred to the TX/RX Controller, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with its status word. The descriptor status indicates a partial frame because of overflow. In such frames, the Frame Length (FL) field in the receive descriptor is invalid. If the RX FIFO is configured to operate in the store-and-forward mode and if the length of the received frame is more than the FIFO size, overflow occurs and all such frames are dropped. During error handling, the DMA flushes the error frame currently being read.

The Receive control logic can filter error and undersized frames if enabled through configuring the FEF or FUF bit of the **EMACDMAOPMODE** register. Filtering must be set before the start address of the frame has been transferred to the TX/RX controller for it to take effect.

### **Receive Word Status**

At the end of an Ethernet frame transfer to the system memory, the TX/RX Controller sends a receive status word, RDES0, to the application. Until the end of the frame transfer, the TX/RX Controller stores the status and frame length in an asynchronous status FIFO whose depth is determined by the size of the RX FIFO (2K) and the minimum size of the frame. If the frame size is 64, then the asynchronous FIFO depth is  $2048/64 = 32$  bytes in length. Note that when the status of a partial frame (because of overflow) is sent to the application, the Frame Length field of RDES0 is not valid and is set to zero.

**Note:** When the timestamp feature is enabled, the receive status field is greater than 32-bits. An extended status bit-field [63:32] provides information about the received Ethernet payload when it is carrying PTP packets or TCP/UDP/ICMP over IP packets. Since the data bus is 32 bits, the status is transferred over two clock cycles.

### 23.3.5.3 MAC Flow Control

Flow control mechanisms can be enabled for both the TX and RX FIFO datapath, depending on the configurations in the **Ethernet MAC Flow Control (EMACFLOWCTL)** register at offset 0x018 and the DUPM bit configuration in the **Ethernet MAC Configuration (EMACCFG)** register at offset 0x000.

**Table 23-29. TX MAC Flow Control**

| TFE bit in EMACFLOWCTL | DUPM bit in EMACCFG | Description                                                                                                                          |
|------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 0                      | X                   | The MAC transmitter does not perform the flow control or backpressure operation.                                                     |
| 1                      | 0                   | The MAC transmitter performs backpressure when the FCBBPA bit in the <b>Ethernet MAC Flow Control (EMACFLOWCTL)</b> register is set. |
| 1                      | 1                   | The MAC transmitter sends a pause frame when the FCBBPA bit in the <b>Ethernet MAC Flow Control (EMACFLOWCTL)</b> register is set.   |

**Table 23-30. RX MAC Flow Control**

| TFE bit in EMACFLOWCTL | DUPM bit in EMACCFG | Description                                                                                                         |
|------------------------|---------------------|---------------------------------------------------------------------------------------------------------------------|
| 0                      | X                   | The MAC receiver does not detect the received Pause frames.                                                         |
| 1                      | 0                   | The MAC receiver does not detect the received Pause frames but recognizes such frames as Control frames.            |
| 1                      | 1                   | The MAC receiver detects or processes the Pause frames and responds to such frames by stopping the MAC transmitter. |

## 23.3.6 MAC Operation

The MAC module enables the CPU to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2008 standard. The MAC supports the interface to the PHY and is comprised of a receive and transmit module whose features are described in the following sections.

### 23.3.6.1 MAC Transmit Module

MAC transmission is initiated when the TX/RX Controller transmits data with the start of frame (SOF) signal asserted. When the SOF signal is detected, the MAC accepts the data and begins transmitting to the PHY. The time required to transmit the frame data after the application initiates transmission varies, depending on delay factors like inter-frame gap (IFG) delay, time to transmit preamble or start of frame data (SFD), and any back-off delays for half-duplex mode. Until then, the MAC does not accept data received from the TX/RX Controller.

After the end-of-frame (EOF) is transferred to the MAC, the MAC completes the normal transmission and gives the status of transmission to the TX/RX Controller. If a normal collision (in half-duplex mode) occurs during transmission, the MAC conveys the transmit status to the TX/RX Controller. It then accepts and drops all further data until the next SOF is received. The TX/RX Controller should retransmit the same frame from SOF on observing a retry request (in the transmit status word) from the MAC. The MAC issues an underflow status if the TX/RX Controller is not able to provide the data continuously during the transmission. During the normal transfer of a frame from the TX/RX Controller, if the MAC receives an SOF without getting an EOF for the previous frame, it ignores the SOF and considers the new frame as a continuation of the previous frame.

If the number of bytes received from memory is less than 60 bytes, zeros are automatically appended to the transmitting frame to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE802.3.

The transmit engine controls the operation of Ethernet frame transmission. Some of the functions of the transmit module include:

- Output of (32-bit) Transmit Status (TDES0) to the application at the end of normal transmission or collision
- Generating preamble and Start of Frame Data (SFD)
- Generating jam pattern in half-duplex mode
- Supporting Jabber time-out
- Supporting flow control
- Generating timestamp information for transmission
- Scheduling frame transmission to satisfy inter-frame gap (IFG) and back-off delays
- Generating CRC and FCS field for Ethernet Frame
- Generating pause frames as necessary in full duplex mode

When a new frame transmission is requested, the MAC transmit module sends out a preamble and SFD, followed by the data in the TX FIFO. The preamble is defined as 7 bytes of 0xAA and the SFD is defined as 1 byte of 0xAB pattern.

The collision window is defined as 1 slot time (512-bit times). If a collision occurs any time from the beginning of the frame to the end of the CRC field, the MAC transmit module sends a 32-bit jam pattern of 0x5555.5555 to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the MAC transmit module completes the transmission of the preamble and SFD, and then sends the jam pattern. If the collision occurs after the collision window and before the end of the FCS field, the MAC transmit module sends a 32-bit jam pattern and sets the late collision bit in the transmit frame status. The jam pattern generation is applicable only to half-duplex mode.

A jabber timer is enabled by default at reset in the MAC module. If the JD bit in the **EMACCFG** register at offset 0x000 is clear and the MAC module has transferred more than 2K bytes, the jabber timer causes the MAC module to stop transmission of Ethernet frames. The timeout is changed to 10 KB when the Jumbo Frame Enable (JFEN) bit is enabled in the **EMACCFG** register.

The MAC transmit module uses a deferral mechanism for flow control (back pressure) in half-duplex mode. When the application requests to stop receiving frames, the transmit module sends a jam pattern of 32 bytes whenever it senses the reception of a frame, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a frame to be transmitted, the frame is scheduled and transmitted even when backpressure is activated. If the backpressure is activated for a long time (more than 16 consecutive collision events occur) then the remote stations abort their transmissions because of excessive collisions.

If IEEE 1588 timestamping is enabled for the transmit frame, the MAC transmit module takes a snapshot of the system time when the start-of-frame data is output on the bus.

### 23.3.6.2 MAC Transmit Module CRC Generator

The Transmit CRC Generator is used to generate the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following generating polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1.$$

The calculated CRC is valid on the next clock after the data is received.

### 23.3.6.3 MAC Receive Module

A receive operation is initiated when the MAC detects start-of-frame data (SFD). The MAC strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field is used to verify the CRC for the frame. The received frame is stored in a buffer until the address filtering is performed. The frame is dropped in the MAC if it fails the address filter.

Some of the functions of the MAC receive module are as follows:

- Stripping the preamble, SFD and carrier extension of the Ethernet frame
- Providing IEEE 1588 timestamping whenever an SFD is detected
- Converting receive nibble data into bytes in MII mode
- Decoding Length/Type field of the Ethernet frame
- Auto-CRC/pad stripping if enabled in the **EMACCFG** register
- Frame data and status buffering for received frames
- Data path conversion of 8-bit data to 32-bit data
- Frame filtering
- Attaching calculated IP checksum input to frame
- Detecting receiving pause frames and pausing the frame transmission for the delay specified withing the received pause frame
- Receive IP Checksum Verification
- Performing destination and source address checking functions on all received frames and reporting the address filtering status to the receive frame controller module.

### 23.3.6.4 MAC Receive Module CRC Generator

The receive CRC Generator is used to generate the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following generating polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The calculated CRC is valid on the next clock after the data is received.

### 23.3.6.5 MAC Receive Frame Controller

If the RA bit is set in the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)** register, offset 0x004, the MAC Receive Frame Controller initiates the data transfer to the RX FIFO as soon as four bytes of Ethernet data are received. At the end of the data transfer, the received frame status that includes the frame filter bits (SA or DA filter fail) and status are also sent. These bits indicate to the application whether the received frame has passed the filter controls. This module does not drop any frame on its own in this mode.

If the RA bit is clear, the MAC Receive Frame Controller performs frame filtering based on the destination/source address (the application still needs to perform another level of filtering if it decides

not to receive any bad frames like runt, CRC error frames, etc.) After receiving the destination or source address bytes, the MAC Receive Frame Controller checks the filter-fail sign for an address match. On detecting a filter-fail, the frame is dropped and not transferred to the application.

**Note:** When the PMT module is configured for power-down mode, all received frames are dropped and not forwarded to the application.

### 23.3.7 IEEE 1588 and Advanced Timestamp Function

The MAC module supports the IEEE 1588-2002 Timestamp Precision Time Protocol (PTP) and the IEEE 1588 Advanced Timestamp features. PTP enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by a local area network supporting multicast messaging. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The PTP is transported over UDP/IP. The system or network is classified into master and slave nodes for distributing the timing and clock information. Figure 23-10 on page 1570 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

**Figure 23-10. Networked Time Synchronization**

As shown in Figure 23-10 on page 1570, the PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t1. This time is captured at the MII interface.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow\_Up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay\_Req message to the master, noting the exact time, t3, at which this frame leaves the MAC.
5. The master receives the message, capturing the exact time, t4, at which it enters its system.
6. The master sends the t4 information to the slave in the Delay\_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet MAC. This timing information is captured and returned to the software for the proper implementation of PTP with high accuracy.

#### 23.3.7.1 System Time Module

The System Time module maintains a 64-bit time and is updated using the MOSC clock source as the PTP clock reference. This time is the source for taking snapshots (timestamps) of the Ethernet frames being transmitted or received. Two methods of updating the system time counter are implemented. The counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the **MAC System Time - Seconds Update (EMACTIMSECU)** register along with the **MAC System Time - Nanoseconds Update (EMACTIMNANOU)** register. For initialization the system time counter is written with the value in these registers, while for system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the slave clock's frequency drift with respect to the master clock is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the **EMACTIMADD** register, as shown in Figure 23-11 on page 1572. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high precision frequency multiplier or divider.

Figure 23-11. System Time Update Using Fine Correction Method

**Note:** The MOSC clock that feeds the PTP reference clock to the System Time Module has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. For course correction methods, the value of MOSC can be anywhere within this range, but for the fine correction method, a 25 MHz value MOSC crystal should be used for the best accuracy.

Initially, the Ethernet's slave clock (from the MOSC) is adjusted with a compensation value (as described in the previous paragraph) which is written to the Timestamp Addend Register (TSAR) field in the **EMACTIMADD** register. This value is calculated as:  $\text{FreqCompensationValue}_0 = \text{TSAR} = 2^{32} / \text{FreqDivisionRatio}$ .

The System Time Module requires a 20-MHz PTP reference clock frequency to achieve 50-ns accuracy in the fine correction method. An addend must be written to the **Ethernet MAC Time Stamp Addend (EMACTIMADD)** register, offset 0x718 to achieve timing synchronization. If the MOSC clock source is 25 MHz, the frequency division ratio (FreqDivisionRatio) of the two is calculated as  $25 \text{ MHz} / 20 \text{ MHz} = 1.25$ . Hence, the default addend value to be set in the register is  $2^{32} / 1.25$  or 0xC000.CCD0. If the reference clock drifts lower, to 24 MHz for example, the ratio is  $24 / 20$ , or 1.2 and the value to set in the addend register is  $2^{32} / 1.20$ , or 0xDFF1.65D2. The software must calculate the drift in frequency based on the Sync messages and update the **EMACTIMADD** register, at offset 0x718, accordingly.

If the master to slave delay is initially assumed to be the same for consecutive Sync messages, then the following steps can be used to calculate a new TSAR value. The following algorithm

calculates the precise master to slave delay value to allow for re-synchronization with the master using the new value:

1. At time  $\text{MasterSyncTime}_n$  the master sends the slave clock a Sync message. The slave receives this message when its local clock is  $\text{SlaveClockTime}_n$  and computes  $\text{MasterClockTime}_n$  as:

$$\text{MasterClockTime}_n = \text{MasterSyncTime}_n + \text{MasterToSlaveDelay}_n$$

2. The master clock count,  $\text{MasterClockCount}_n$ , for the current Sync cycle is given by:

$$\text{MasterClockCount}_n = \text{MasterClockTime}_n - \text{MasterClockTime}_{n-1}$$

This assumes that the  $\text{MasterToSlaveDelay}$  is the same for Sync cycles  $n$  and  $n-1$ .

3. The slave clock count for current Sync cycle,  $\text{SlaveClockCount}_n$  is given by:

$$\text{SlaveClockCount}_n = \text{SlaveClockTime}_n - \text{SlaveClockTime}_{n-1}$$

4. The difference between the master and slave clock counts for the current Sync cycle,  $\text{ClockDiffCount}_n$ , is given by:

$$\text{ClockDiffCount}_n = \text{MasterClockCount}_n - \text{SlaveClockCount}_n$$

5. The frequency-scaling factor for the slave clock,  $\text{FreqScaleFactor}_n$  is given by:

$$\text{FreqScaleFactor}_n = (\text{MasterClockCount}_n + \text{ClockDiffCount}_n) / \text{SlaveClockCount}_n$$

6. The frequency compensation value,  $\text{FreqCompensationValue}$ , to be written in the TSAR field of the EACTIMADD register is:

$$\text{FreqCompensationValue}_n = \text{FreqScaleFactor}_n * \text{FreqCompensationValue}_{n-1}$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more Sync cycles.

### 23.3.7.2 Transmit Timestamping

The MAC captures a timestamp when the Start Frame Delimiter (SFD) of a frame is sent. The transmit frames are marked to indicate whether a timestamp should be captured for that frame and written to the extended transmit descriptors that support timestamping. The MAC returns the timestamp automatically to the corresponding transmit descriptor, thus connecting the timestamp with the specific PTP frame. The 64-bit timestamp information is written to the TDES2 and TDES3 fields.

**Note:** When the enhanced descriptor size is selected by setting the ATDS bit in the **EMACDMABUSMOD** register, a larger descriptor is used and the MAC writes the 64-bit timestamp information to TDES6 and TDES7, respectively.

### 23.3.7.3 Receive Timestamping

The MAC captures the timestamp of all received frames. The MAC does not process the received frames to identify the PTP frames in default timestamping mode (when Advanced Timestamp is disabled). The MAC gives the timestamp and the corresponding status to the TX/RX Controller along with the EOF data. The TX/RX Controller validates and indicates the availability of the timestamp so that the DMA can return the timestamp to the corresponding receive descriptor. The 64-bit timestamp information is written to the RDES2 and RDES3 fields. The timestamp is written

only to the receive descriptor for which the Last Descriptor status field has been set to 1 (the EOF marker). When the timestamp is not available (for example, because of an RX FIFO overflow), an all '1s' pattern is written to the descriptors (RDES2 and RDES3), indicating that the timestamp is not correct. If timestamping is disabled, the DMA does not alter RDES2 or RDES3.

**Note:** When the enhanced descriptor size is selected by setting the ATDS bit in the **EMACDMABUSMOD** register, the 64-bit timestamp is written to RDES6 and RDES7, respectively. RDES0[7] indicates whether the timestamp is updated in RDES6 and RDES7.

#### 23.3.7.4 Timestamp Error Margin

According to the IEEE 1588 specifications, a timestamp must be captured at the SFD of the transmitted and received frames at the MAC interface. Because the reference timing source, MOSC, is taken as different from MAC reference clocks, a small error margin is introduced, because of the transfer of information across asynchronous clock domains. In the transmit path, the captured and reported timestamp has a maximum error margin of 2 PTP (MOSC) clocks. It means that the captured timestamp has the reference timing source (MOSC) value that is given within 2 clocks after the SFD has been transmitted to the PHY. Similarly, in the receive path, the error margin is 3 MAC reference clocks, plus up to 2 PTP clocks. The error margin of the three MAC reference clocks can be ignored by assuming that this constant delay is present in the system (or link) before the SFD data reaches the interface of MAC.

**Note:** The MII clock is provided by the external PHY through EN0RXCK and EN0TXCK.

**Note:** When IEEE 1588 timestamping is enabled with internal timestamp, use a PTP clock frequency that is greater than 5 MHz. This is because the SSINC field in the **EMACSUBSECINC** register limits the PTP frequency that can be used to ~4 MHz.

#### 23.3.7.5 IEEE 1588-2008 Advanced Timestamps

In addition to the basic timestamp features mentioned in IEEE 1588-2002 Timestamps, the Ethernet Controller supports the following advanced timestamp features defined in the IEEE 1588-2008 standard:

- Supports the IEEE 1588-2008 (version 2) timestamp format.
- Provides an option to take snapshot of all frames or only PTP type frames.
- Provides an option to take snapshot of only event messages.
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end, and peer-to-peer.
- Provides an option to select the node to be a master or slave clock.
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.
- Provides an option to measure sub-second time in digital or binary format.

##### **Peer-to-Peer Transparent Clock Message Support**

The IEEE 1588-2008 version supports Peer-to-Peer PTP (Pdelay) message in addition to SYNC, Delay Request, Follow-up, and Delay Response messages. Figure 23-12 on page 1575 shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

**Figure 23-12. Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction**

As shown in Figure 23-12 on page 1575, the propagation delay is calculated in the following way:

1. Port-1 issues a  $Pdelay\_Req$  message and generates a timestamp,  $t_1$ , for the  $Pdelay\_Req$  message.
2. Port-2 receives the  $Pdelay\_Req$  message and generates a timestamp,  $t_2$ , for this message.
3. Port-2 returns a  $Pdelay\_Resp$  message and generates a timestamp,  $t_3$ , for this message.

To minimize errors because of any frequency offset between the two ports, Port-2 returns the  $Pdelay\_Resp$  message as quickly as possible after the receipt of the  $Pdelay\_Req$  message. The Port-2 returns any one of the following:

- The difference between the timestamps  $t_2$  and  $t_3$  in the  $Pdelay\_Resp$  message.
  - The difference between the timestamps  $t_2$  and  $t_3$  in the  $Pdelay\_Resp\_Follow\_Up$  message.
  - The timestamps  $t_2$  and  $t_3$  in the  $Pdelay\_Resp$  and  $Pdelay\_Resp\_Follow\_Up$  messages respectively.
4. Port-1 generates a timestamp,  $t_4$ , on receiving the  $Pdelay\_Resp$  message.
  5. Port-1 uses all four timestamps to compute the mean link delay.

#### **Advanced Timestamp Supported Clock Types**

The Advance Timestamp Module supports an ordinary clock as defined by the IEEE 1588-2008 standard. The characteristics of this clock is as follows:

- Sending and receiving of PTP messages. The timestamp snapshot can be controlled through the **Ethernet MAC Timestamp Control (EMACTIMSTCTRL)** register, offset 0x700. Timestamp snapshots can be for Sync messages.
- Maintaining the data sets such as timestamp values.

For an ordinary clock, snapshots can be taken of either version 1 or version 2 PTP types but not both. Selecting between the two is controlled by the PTPVER2 bit of the **EMACTIMSTCTRL** register.

### ***PTP Processing and Control***

There are fields in an Ethernet Payload that the Ethernet Controller can use to detect the PTP packet type and control the snapshot to be taken. These fields are different depending on whether the PTP frames are:

- PTP frames over IPv4
- PTP frames over IPv6
- PTP frames over Ethernet

The PTPIPv4, PTPIPv6 or PTPETH bits can be set depending on which PTP processing is required.

### ***Reference Timing Source***

The MAC supports the following reference timing source features defined in the IEEE 1588-2008 standard:

- 80-bit timestamp
- Fixed Pulse-Per-Second PPS0 Output
- Flexible Pulse-Per-Second PPS0 Output

### ***80-Bit Timestamp***

The MAC supports an 80-bit timestamp with a lengthened seconds integer portion which is 48-bits wide. The **Ethernet MAC System Time - Seconds (EMACTIMSEC)** register at offset 0x708 and the **Ethernet MAC System Time-Higher Word Seconds (EMACHWORDSEC)** register at offset 0x724 comprise the seconds count. The 32-bit **Ethernet MAC System Time - Nanoseconds (EMACTIMNANO)** register contains the fractional portion of the timestamp units of nanoseconds. The nanoseconds register supports the following two modes:

- Digital rollover mode: In digital rollover mode, the maximum value in the nanoseconds field is 0x3B9A\_C9FF, that is, (10e9-1) nanoseconds.
- Binary rollover mode: In binary rollover mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF\_FFFF. Accuracy is ~0.466 ns per bit.

Digital or binary rollover mode can be selected by programming the DGTLBIN bit of the **EMACTIMSTCTRL** register. Note that the timestamp maintained in the MAC is still 64-bits wide, but that the overflow to the upper 16-bits seconds register happens once in 130 years.

**Fixed Pulse-Per-Second Output**

The Ethernet MAC module supports a pulse-per-second output feature such that the signal, EN0PPS, can indicate one second intervals. The frequency of the EN0PPS output can be changed by setting the PPSCTRL bit field of the **Ethernet MAC PPS Control (EMACPPSCTRL)** register, offset 0x72C.

**Flexible Pulse-Per-Second Output**

The Ethernet MAC also provides the ability to control the following features of the EN0PPS output:

- Start or stop time
- The start point of a single pulse and the start and stop points of the pulse train in terms of a 64-bit system time. The **EMACTIMESEC** and **EMACTIMNANO** registers are used to program the start and stop time.
- The stop time can be programmed in advance of starting.
- The signal width. The rising edge and the corresponding falling edge of the EN0PPS output can be programmed in terms of number of units of sub-second increment value programmed in the **Ethernet MAC Sub-Second Increment (EMACSUBSECINC)** register, offset 0x704.
- The signal interval. The time between the rising edges of EN0PPS signal, in terms of number of units of sub-second increment value can be programmed in the **Ethernet MAC PPS0 Interval (EMACPPS0INTVL)** register, offset 0x760. You can program the interval between pulses from 1 to  $2^{32}-1$  units of sub-second increment value.
- Cancellation of the programmed EN0PPS start or stop request.
- Error indication if the start or stop time being programmed has already passed.

The start time can be programmed in the **EMACTARGSEC** and **EMACTARGNANO** registers. The TRGTBUSY bit in the **EMACTARGNANO** register indicates when the value is synchronized to the PTP clock domain. When this bit is clear, a new start time can be programmed, even before the earlier start time has elapsed. The start or stop time should be programmed with advanced system time to ensure proper EN0PPS signal output. If the application programs a start or stop time that has already elapsed, then the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

For a flexible EN0PPS output, the **EMACPPS0INTVL** and **EMACPPS0WIDTH** registers can be configured. The PPS0WIDTH and PPS0INT fields are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a EN0PPS pulse width of 80 ns and interval of 120 ns, with the PTP reference clock of 25MHz, you should program the width and interval to values 1 and 2, respectively. Note that the PPS0WIDTH and PPS0INT value must be programmed as one less than the required interval. Before giving the command to trigger a pulse or pulse train on the EN0PPS output, the interval and width of the PPS signal output should be programmed or updated.

**Advanced Timestamp Transmit Path Functions**

The only aspect of the transmit path that changes with advanced timestamp is the descriptor, which extends to 32-bytes long.

When you enable the advanced timestamp feature, the structure of the descriptor changes. The advanced timestamp feature is supported only through the enhanced descriptors format. The descriptor is 32-bytes long (eight words) and the snapshot of the timestamp is written in descriptor TDES6 and TDES7.

#### **Advanced Timestamp Receive Path Functions**

When the advanced timestamp feature is enabled, the MAC processes the received frames to identify valid PTP frames. The snapshot of the time sent to the application can be configured to:

- Enable snapshot for all frames
- Enable snapshot for IEEE 1588 version 2 or version 1 timestamp.
- Enable snapshot for PTP frames transmitted directly over Ethernet or UDP-IP-Ethernet.
- Enable timestamp snapshot for the received frame for IPv4 or IPv6.
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY\_REQ, PDELAY\_REQ, or PDELAY\_RESP).
- Enable the node to be a master or slave and select the snapshot type. This controls the type of messages for which snapshots are taken.

The MAC provides the timestamp, along with EOF to the TX/RX Controller. The DMA returns the timestamp inside the corresponding receive descriptor.

### **23.3.8 Frame Filtering**

The following types of filtering are available for receive frames:

- Source Address (SA) or Destination Address (DA) filtering
- VLAN Filtering

The frame filtering supports a sequence where the packet is not forwarded to VLAN filtering if it does not pass the SA or DA filtering first.

#### **23.3.8.1 VLAN Filtering**

The Ethernet MAC provides VLAN Tag Perfect Filtering and VLAN Tag Hash Filtering. In VLAN tag perfect filtering, the MAC compares the VLAN tag of the received frame and provides the VLAN frame status to the application. Based on the programmed mode of the ETV bit in the **EMACVLANTG** register, the MAC compares the lower 12 bits or all 16 bits of the received VLAN tag to determine the perfect match. If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged frames along with VLAN tag match status and drops the VLAN frames that do not match. Inverse matching for VLAN frames can also be enabled by setting the VTIM bit of the **Ethernet MAC VLAN Tag (EMACVLANTG)** register, offset 0x01C. In addition, matching of S-VLAN tagged frames along with the default C-VLAN tagged frames can be enabled by setting the ESVL bit of the **EMACVLANTG** register. The VLAN frame status bit (Bit 10 of RDES0) indicates the VLAN tag match status for the matched frames.

**Note:** The Source or Destination Address filter has precedence over the VLAN tag filters. A frame which fails the Source or Destination Address filter is dropped irrespective of the VLAN tag filter results.

The MAC provides VLAN tag hash filtering with a 16-bit Hash table. The MAC performs the VLAN hash matching based on the VTHM bit of the **EMACVLANTG** register. If the VTHM bit is set, the most significant four bits of VLAN tag's CRC-32 are used to index the content of the **Ethernet MAC VLAN Hash Table (EMACVLANHASH)** register, offset 0x588. A value of 1 in the **EMACVLANHASH** register, corresponding to the index, indicates that the VLAN tag of the frame matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged frame should be dropped. The MAC also supports the inverse matching of the VLAN frames. In the inverse matching mode, when the VLAN tag of a frame matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a frame is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch. Table 23-31 on page 1579 shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of the **EMACFRAMEFLTR** register is set, all frames are received and the VLAN match status is indicated in Bit 10 of Receive Descriptor word 0 (RDES0). When the RA bit is not set and the VTFE bit in the **EMACFRAMEFLTR** register is set, the frame is dropped if the final VLAN match status is fail. In Table 23-31 on page 1579, value X means that this column can have any value. When the VL field is programmed to 0x0 in **EMACVLANTG** register, all VLAN-tagged frames are considered as perfect matched but the status of the VLAN hash match depends on the VLAN hash enable (VTHM) bit and VLAN inverse filter (VTIM) bit.

**Table 23-31. VLAN Match Status**

| VLAN ID (VL field) | VLAN Perfect Filter Match Status (VPF) | VLAN HASH Enable bit (HPF bit in EMACFRAMEFLTR) | VLAN Hash Filter Match Status (VTHM) | VLAN Inverse Filter Bit (VTIM) | Final VLAN Match Status |
|--------------------|----------------------------------------|-------------------------------------------------|--------------------------------------|--------------------------------|-------------------------|
| VL = 0             | Pass                                   | 0                                               | X                                    | X                              | Pass                    |
|                    | Pass                                   | 1                                               | X                                    | 0                              | Pass                    |

|                    | Fail                                   | 0                                               | X                                    | 1                              | Pass                    |
|                    | Pass                                   | X                                               | X                                    | 1                              | Fail                    |
|                    | Fail                                   | 1                                               | Pass                                 | 1                              | Fail                    |
|                    | Fail                                   | 1                                               | Fail                                 | 1                              | Pass                    |

### 23.3.9 Source Address, VLAN, and CRC Insertion, Replacement or Deletion

The MAC supports the following functions for transmit frames:

- Source Address Insertion or replacement
- VLAN Insertion, Replacement or Deletion
- CRC Replacement

#### 23.3.9.1 Source Address Insertion or Replacement

Software can use the SA insertion or replacement feature to instruct the MAC to do the following for transmit frames:

- Insert the content of the MAC Address Registers in the SA field.
- Replace the content of the SA field with the content of the MAC Address Registers.

The software can enable the SA insertion or replacement for all transmitted frames or selective frames:

- To enable SA insertion or replacement feature for all frames, program the SADDR field of the **Ethernet MAC Configuration (EMACCFG)** register.
- To enable SA insertion or replacement for selective frames, program the SA Insertion Control field (TDES1 Bits [31:29]) in the first transmit descriptor of the frame. When Bit 31 of TDES1 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 31 of TDES1 is reset, it indicates insertion or replacement by MAC Address 0 registers.

When SA insertion is enabled, the application should ensure that the frames that are sent to the MAC do not have the SA field. The MAC does not check the presence of SA field in the transmit frame and just inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application should ensure that the frames that are sent to the MAC have the SA field. The MAC just replaces the six bytes, following the Destination Address field in the transmit frame, with the content of the MAC Address Registers.

### 23.3.9.2 VLAN Insertion, Replacement or Deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for transmit frames:

- Insert or replace the VLAN Type field (C-VLAN or S-VLAN indicated by the CSVL bit of the **Ethernet MAC VLAN Tag Inclusion or Replacement (EMACVLNINCREP)**, MAC offset 0x584) and the VLAN Tag field in the transmit frame with the VLT field of the **EMACVLNINCREP** register.
- Delete the VLAN Type and VLAN Tag fields in the transmit frame.

The software can enable the VLAN insertion, replacement, or deletion feature for all transmitted frames or selective frames. To enable this function for all transmit frames, configure the VLT field in the **EMACVLNINCREP** register.

When VLAN replacement or deletion is enabled, the MAC checks the presence of the VLAN Type field (0x8100 or 0x88a8), after the Destination address (DA) and SA fields, in the transmit frame. The replace or delete operation does not occur if the VLAN Type field is not detected in the two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the transmit frame and just inserts the VLAN Type and VLAN Tag fields.

### 23.3.9.3 CRC Replacement

The software can use the CRC replacement feature to instruct the MAC to replace the FCS field in the transmit frame with the CRC computed by the MAC. This feature works on a per-frame basis. The CRC replacement control field in the Transmit Descriptor Word 0 (TDES0) can be programmed to enable this for a frame. This feature is valid only when the Disable CRC control (Bit 27 of TDES0) is enabled. If SA or VLAN insertion control is enabled, the MAC appends or replaces the FCS field with the computed CRC when Disable CRC Control is enabled or disabled, respectively.

**Table 23-32. CRC Replacement Based on Bit 27 and Bit 24 of TDES0**

| Bit 27 (DC) | Bit 24 (CRCR) | Description                                                                                  |
|-------------|---------------|----------------------------------------------------------------------------------------------|
| 0           | X             | Append CRC<br>When DC= 0, the MAC appends the computed CRC irrespective of the CRCR setting. |
| 1           | 1             | Replace CRC                                                                                  |
| 1           | 0             | No operation (user has appended CRC)                                                         |

### 23.3.10 Checksum Offload Engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the MAC Checksum Offload Engine (COE) supports checksum calculation and insertion in the transmit path, and error detection in the receive path.

#### 23.3.10.1 Transmit Checksum Offload Engine

The checksum for TCP, UDP, or ICMP is calculated over a complete frame, and then inserted into its corresponding header field. Because of this requirement this function is enabled only when the TX FIFO is configured for the store-and-forward mode (the TSF bit is set in the **EMACDMAOPMODE** register).

**Note:** The TX FIFO must be deep enough to store a complete frame before the frame is transferred to the MAC when the checksum offload is being used. If space is not available to accept the programmed burst length of data, the TX/RX Controller starts reading to avoid deadlock. When reading starts, the checksum offload fails and the consequently all succeeding frames may be corrupted because of improper recovery. Therefore, checksum insertion must only be enabled in frames that are less than  $[2048 - ((PBL + 3) * 4)]$  bytes in size, where PBL is the Programmable Burst Length field in the **EMACDMABUSMOD** register.

#### 23.3.10.2 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The checksum offload engine detects an IPv4 datagram when the Ethernet frame's Type field has the value 0x0800 and the IP datagram's Version field has the value 0x4. The input frame's checksum field is ignored during calculation and replaced with the calculated value. IPv6 headers do not have a checksum field. Therefore, the checksum offload does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 16 in TDES0). This status bit is set whenever the values of the Ethernet Type field and the IP header's Version field are not consistent, or when the Ethernet frame does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the IP header's Version field is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total frame length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:

- The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
- The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

If the checksum offload engine detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

### 23.3.11 MAC Management Counters

The MAC Management Counters (MMC) module maintains a set of registers for gathering statistics on the received and transmitted frames. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (one for receive and one for transmit), and two 32-bit registers containing masks for the Interrupt register (one for receive and one for transmit). The MMC counters are free running and start counting when a corresponding frame is received or transmitted. The MMC counter registers provided are as follows:

- **Ethernet MAC Transmit Frame Count for Good and Bad Frames (EMACTXCNTGB)**
- **Ethernet MAC Transmit Frame Count for Frames Transmitted after Single Collision (EMACTXCNTSCOL)**
- **Ethernet MAC Transmit Frame Count for Frames Transmitted after Multiple Collisions (EMACTXCNTMCOL)**
- **Ethernet MAC Transmit Octet Count Good (EMACTXOCTCNTG)**
- **Ethernet MAC Receive Frame Count for Good and Bad Frames (EMACRXCNTGB)**
- **Ethernet MAC Receive Frame Count for CRC Error Frames (EMACRXCNTCRCERR)**
- **Ethernet MAC Receive Frame Count for Alignment Error Frames (EMACRXCNTALGNERR)**
- **Ethernet MAC Receive Frame Count for Good Unicast Frames (EMACRXCNTGUNI)**

### 23.3.12 Power Management Module

The power management (PMT) module supports the reception of network remote wake-up frames and AMD Magic Packet™ frames. The PMT module does not perform the clock gate function, but generates interrupts for remote wake-up frames and magic packets that the MAC receives.

When the application enables the power-down mode in the PMT module by setting the PWRDWN bit in the **Ethernet MAC PMT Control and Status Register (EMACPMTCTLSTAT)** register, MAC offset 0x02C, the MAC drops all received frames and does not forward any frame to the TX/RX Controller Rx FIFO or the application. The MAC comes out of the power-down mode only when a magic packet or a remote wake-up frame is received and the corresponding detection is enabled.

#### 23.3.12.1 Remote Wake-Up

The Remote Wake-Up register bank is made up of eight 32-bit registers. It is loaded by writing the **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register eight times. To load values in the **EMACRWUFF** register, the entire register must be written. The first write is assigned to register 0 of the bank, then register 1 and so on. The **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register is read the same way. The current pointer value of the bank is updated in the Remote Wake-Up FIFO Pointer (RWKPTR) field of the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register.

**Figure 23-13. Wake-Up Frame Filter Register Bank**

|                    |                  |                 |                  |                   |                  |                 |                  |
|--------------------|------------------|-----------------|------------------|-------------------|------------------|-----------------|------------------|
| Filter 0 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Filter 1 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Filter 2 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Filter 3 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| RSVD               | Filter 3 Command | RSVD            | Filter 2 Command | RSVD              | Filter 1 Command | RSVD            | Filter 0 Command |
| Filter 3 Offset    |                  | Filter 2 Offset |                  | Filter 1 Offset   |                  | Filter 0 Offset |                  |
| Filter 1 CRC - 16  |                  |                 |                  | Filter 0 CRC - 16 |                  |                 |                  |
| Filter 3 CRC - 16  |                  |                 |                  | Filter 2 CRC - 16 |                  |                 |                  |

**Filter n Byte Mask**

The Filter n Byte Mask registers of the Remote Wake-Up register define the bytes of the frame that are examined by filter n (0, 1, 2, and 3) in order to determine whether or not a frame is a remote wake-up frame. The most significant bit (bit 31) of each mask must be zero. Bits [30:0] are the Byte Mask. If bit, j, of the Byte Mask is set, then the CRC block processes the Filter n Offset + j of the incoming frame; otherwise Filter n Offset + j is ignored.

**Filter n Command**

The 4-bit Filter n Command field controls the Filter n operation in the following way:

- Filter n Command Bit 3 specifies the address type of the pattern. When the bit is set, the pattern applies to only multicast frames; when the bit is reset, the pattern applies only to unicast frame.
- Filter n Command Bit 2 and Bit 1 are reserved.
- Filter n Command Bit 0 is the enable for Filter n. If bit 0 is not set, filter n is disabled.

**Filter n Offset**

The Filter n Offset register defines the offset (within the frame) from which the filter n examines the frames. This 8-bit pattern offset is the offset for the filter n first byte to be examined. The minimum allowed offset is 12, which refers to the 13th byte of the frame. The offset value 0 refers to the first byte of the frame.

**Filter n CRC-16**

The Filter n CRC-16 register contains the CRC\_16 value calculated from the pattern and the byte mask programmed to the wake-up filter register block.

**23.3.12.2 Remote Wake-Up Frame Detection**

When the MAC is in sleep mode and the remote wake-up frame enable bit, WUPFREN, is set in the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register, the normal operation is

resumed after a remote wake-up frame is received. The application writes all eight wake-up filter registers, by performing eight sequential writes to the **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register. The Power Management (PMT) block supports four programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of Filter Command, and if Filter CRC-16 matches the CRC of the incoming pattern, then the MAC identifies the frame as wake-up frame. The Filter Offset determines the offset from which the frame is to be examined. The Filter Byte Mask determines which bytes of the frame must be examined. The 31st bit of Byte Mask must be set to zero. The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The remote wake-up frame is checked only for length error, FCS error, dribble bit error, MII error, and collision. In addition, the remote wake-up frame is checked to ensure that it is not a runt frame. Even if the remote wakeup frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. The remote wake-up frame detection is updated in the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register for every remote wake-up frame received. If the PMT interrupt is enabled in the **Ethernet MAC Interrupt Mask (EMACIM)** register, a PMT interrupt is asserted and the **EMACPMTCTLSTAT** register can be read to determine reception of a remote wake-up frame.

### 23.3.12.3 Magic Packet Detection

The magic packet frame is based on a method that uses Advanced Micro Device's magic packet technology to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network. The MAC checks only those magic packets that are addressed to the MAC or a broadcast address to determine whether these packets meet the wake-up requirements. The magic packets that pass the address filtering (unicast or broadcast) are checked to determine whether they meet the remote wake-up frame data format of 6 bytes of all ones followed by a MAC Address appearing 16 times. The application enables the magic packet wake-up by setting the magic packet enable bit, MGKPKTEN, of the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register. The power management block constantly monitors each frame addressed to the node for a specific magic packet pattern. Each frame received is checked for a 0xFFFF.FFFF.FFFF pattern following the destination and source address field. The power management block then checks the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the PMT block again scans the 0xFFFF.FFFF.FFFF pattern in the incoming frame. The 16 repetitions can be anywhere in the frame, but must be preceded by the synchronization stream (0xFFFF.FFFF.FFFF). The device can also accept a multicast frame, as long as the 16 duplications of the MAC address are detected. If the MAC address of a node is 0x0011.2233.4455, then the MAC scans for the following data sequence:

```
Destination Address Source Address ..... FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 ...CRC
```

The magic packet detection is updated in the **EMACPMTCTLSTAT** register for the received magic packet. If the PMT interrupt is enabled in the **Ethernet MAC Interrupt Mask (EMACIM)** register, a PMT interrupt is asserted and the **EMACPMTCTLSTAT** register can be read to determine whether a magic packet frame has been received.

### 23.3.12.4 Power Management Interrupts

The PMT interrupt signal can be asserted when a valid remote wake-up frame or magic packet is received. The PMT interrupt signal restores the application clock and TX clock to the MAC. When the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register is read, the PMT interrupt is cleared in the **EMACRIS** register at least after four clock cycles of RX clock. When software resets the PWRDWN bit in the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register, the MAC comes out of the power-down mode, but this event does not generate at PMT interrupt.

### 23.3.12.5 Power-Down/Wake-Up Sequence

The recommended power-down and wake-up sequence is as follows:

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. These transmissions can be detected when TI is set in the **Ethernet MAC DMA Interrupt Status (EMACDMARIS)** register.
2. Disable the MAC transmit and receive state machine by clearing the TE and RE bits in the **Ethernet MAC Configuration (EMACCFG)** register.
3. Wait until the RX DMA empties all the frames from the Rx FIFO to system memory by polling the RXF field of the **Ethernet MAC Status (EMACSTATUS)** register.
4. Enable a power management mode by setting the magic packet, global unicast or remote wake-up enable bit in the **EMACPMTCTLSTAT** register.
5. Enable the MAC receive state machine in the **EMACCFG** register and enter the Power-Down mode by setting the PWRDWN bit in the **EMACPMTCTLSTAT** register.
6. On receiving a valid remote wake-up frame, the PMT interrupt is set in the **EMACRIS** register and the Ethernet MAC exits the Power-Down mode.
7. Read the **EMACPMTCTLSTAT** register to clear the PMT interrupt, then enable the other modules in the system and resume normal operation.

### 23.3.13 Serial Management Interface

The Ethernet MAC has the ability to program an external PHY through the external EN0MDIO and EN0MDC signals. The EN0MDC signal is a 2.5 MHz clock that is sourced from System Clock (SYSCLK) and then divided down to the required frequency by programming the CR field in the **Ethernet MAC MII Address (EMACMIIADDR)** register. The available addresses for the PHY are 0x01 to 1F.

### 23.3.14 Reduced Media Independent Interface (RMII)

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Ethernet MACs. According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. In devices incorporating multiple MAC or PHY interfaces such as switches, the number of pins adds significant cost with increase in port count. The RMII specification addresses this problem by reducing the pin count to 7 for each port — a 62.5% decrease in pin count.

The RMII module has the following features:

- Supports both 10-Mbps and 100-Mbps operating rates
- Provides independent, two-bit wide transmit and receive paths

Each nibble is transmitted on the RMII two bits at a time. For a nibble {D3, D2, D1, D0}, the data is transferred as {D1, D0} followed by {D3, D2}.

### 23.3.15 Interrupt Configuration

Interrupts can be generated from the MAC as a result of various events in the MAC and sub-modules. MAC interrupts are enabled or disabled in the **Ethernet MAC Interrupt Mask (EMACIM)** register, MAC offset 0x03C. Each interrupt event can be masked by setting the corresponding mask bit in the **EMACIM** register.

The interrupt register bits in the **Ethernet MAC Raw Interrupt Status (EMACRIS)** register only indicate the sub-module from which the event is reported. The application must read the corresponding status registers to clear the interrupt.

## 23.4 EMAC Initialization and Configuration

The EMAC interface defaults to MII mode. To initialize the RMII interface:

1. The MAC module and registers are enabled and powered at reset. When reset has completed, the application should enable the clock to the Ethernet MAC by setting the R0 bit in the **Ethernet Controller Run Mode Clock Gating Control (RCGCEMAC)** register at System Control Module offset 0x69C.
2. Enable the external clock source input to the RMII interface signal EN0RREF\_CLK by setting both the ECEXT and CLKEN bit in the in the **Ethernet Clock Configuration (EMACCC)** register at offset 0xFC8. The external clock source must be 50 MHz with a frequency tolerance of 50 PPM.
3. Select the RMII interface by programming the PINTFS bit field to 0x4 in the **Ethernet Peripheral Configuration (EMACPC)** register at offset 0xFC4.
4. Reset the Ethernet MAC to latch the new RMII configuration by setting the SWR bit in the **EMACDMABUSMOD** register. This bit resets the Ethernet MAC registers in addition to configuring the RMII interface. Software must poll the SWR bit to determine when the new configuration has been registered.

After this configuration is active, if the Ethernet MAC is reset by setting the R0 bit in the **Ethernet MAC Software Reset (SREMAC)** register in the System Control Module, then the interface is set back to its default MII configuration. In this case, the steps listed above must be repeated to return to an RMII interface.

The Initialization for the DMA for the Ethernet MAC is as follows:

1. Write to the Ethernet **MAC DMA Bus Mode (EMACDMABUSMOD)** register to set Host bus parameters.
2. Write to the Ethernet **MAC DMA Interrupt Mask Register (EMACDMAIM)** register to mask unnecessary interrupt causes.
3. Create the transmit and receive descriptor lists and then write to the **Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR)** register and the **Ethernet MAC Transmit Descriptor List Address (EMACTXDLADDR)** register providing the DMA with the starting address of each list.

4. Write to the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)** register, the **Ethernet MAC Hash Table High (EMACHASHTBLH)** and the **Ethernet MAC Hash Table Low (EMACHASHTBLL)** for desired filtering options.
5. Write to the **Ethernet MAC Configuration Register (EMACCFG)** to configure the operating mode and enable the transmit operation.
6. Program Bit 15 (PS) and Bit 11 (DM) of the **EMACCFG** register based on the line status received or read from the PHY status register after auto-negotiation.
7. Write to the **Ethernet MAC DMA Operation Mode (EMACDMAOPMODE)** register to set Bits 13 and 1 to start transmission and reception.
8. Write to the **EMACCFG** register to enable the receive operation.

The Transmit and Receive engines enter the Running state and attempt to acquire descriptors from the respective descriptor lists. The Receive and Transmit engines then begin processing Receive and Transmit operations. The Transmit and Receive processes are independent of each other and can be started or stopped separately.

## 23.5 Register Map

Table 23-33 on page 1587 lists the Ethernet Controller MAC registers. For the MAC registers, the offset listed is a hexadecimal increment to the MAC base address of 0x400E.C000.

The *IEEE 802.3* standard specifies a register set for controlling and gathering status from the PHY layer. The registers are collectively known as the MII Management registers.

The **Ethernet MAC MII Address (EMACMIADDR)** register, offset 0x010, is used to access MII Management registers on the external PHY device. The PLA field in the **EMACMIADDR** register supports PHY addresses 1 to 31.

**Table 23-33. Ethernet Register Map**

| Offset | Name           | Type | Reset       | Description                                  | See page |

## 23.6 Ethernet MAC Register Descriptions

This section lists and describes the MAC registers, in numerical order by address offset.

## Register 1: Ethernet MAC Configuration (EMACCFG), offset 0x000

The **EMACCFG** register establishes receive and transmit operating modes. Note that the TWOKPEN bit is only applicable when the JFEN bit is 0.

### Ethernet MAC Configuration (EMACCFG)

Base 0x400E.C000

Offset 0x000

Type RW, reset 0x0000.8000

|       | 31       | 30    | 29  | 28     | 27      | 26       | 25  | 24       | 23    | 22 | 21       | 20   | 19  | 18 | 17     | 16     |

| 4         | DC   | RW   | 0x0   | <p><b>Deferral Check</b></p> <p>When this bit is set, the deferral check function is enabled in the MAC.</p> <p>When the transmit state machine is deferred for more than 24,288 bit times, the MAC issues a Frame Abort status, and sets the excessive deferral error bit (EXDEFF) in the <b>MAC MMC Transmit Interrupt (EMACMMCTXRIS)</b> Register.</p> <p>If the Jumbo frame mode (JFEN) is enabled, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on the MII.</p> <p>The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and then the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0 and it is restarted.</p> <p>When this bit is clear, the deferral check function is disabled and the EMAC defers until the CRS signal goes inactive.</p> <p><b>Note:</b> This bit is only applicable in half-duplex mode.</p> <p>Value Description</p> <p>0 Deferral check function is disabled.</p> <p>1 Deferral check function is enabled.</p> |

**Register 2: Ethernet MAC Frame Filter (EMACFRAMEFLTR), offset 0x004**

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

**Ethernet MAC Frame Filter (EMACFRAMEFLTR)**

Base 0x400E.C000

Offset 0x004

Type RW, reset 0x0000.0000

### Register 3: Ethernet MAC Hash Table High (EMACHASHTBLH), offset 0x008

The 64-bit Hash table is used for group address filtering. For hash filtering, the contents of the Destination Address (DA) in the incoming frame is passed through the CRC logic, and the upper 6 bits of the CRC register are used to index the contents of the Hash table. The most significant bit determines the register to be used (**Ethernet MAC Hash Table High (EMACHASHTBLH)** or **Ethernet MAC Hash Table Low (EMACHASHTBL)**), and the other five bits determine which bit within the register. A hash value of 5b'00000 selects bit 0 of the selected register, and a value of 5b'11111 selects bit 31 of the selected register.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in Step 1.
3. Take the upper 6 bits from the value obtained in Step 2.

For example, if the DA of the incoming frame is received as 0x1F52419CB6AF, then the internally calculated 6-bit Hash value is 0x2C and Bit 12 of **EMACHASHTBLH** register is checked for filtering. If the DA of the incoming frame is received as 0xA00A98000045, then the calculated 6-bit Hash value is 0x07 and Bit 7 of Hash Table Low register is checked for filtering.

If the corresponding bit value of the register is 0x1, the frame is accepted. Otherwise, it is rejected. If the PM (Pass All Multicast) bit is set in the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)** register, then all multicast frames are accepted regardless of the multicast hash values.

#### Ethernet MAC Hash Table High (EMACHASHTBLH)

Base 0x400E.C000

Offset 0x008

| 0         | MIIB | RW   | 0x0   | <p>MII Busy</p> <p>Indicates whether the MII is busy with a read or write access.</p> <p>This bit should read logic 0 before writing to the <b>EMACMIADDR</b> register or the <b>EMACMIIDATA</b> register. During a PHY register access, the software sets this bit to indicate that a read or write access is in progress.</p> <p>The <b>EMACMIIDATA</b> register is invalid until this bit is cleared by the MAC. Therefore, <b>EMACMIIDATA</b> should be kept valid until the MAC clears this bit during a PHY Write operation. Similarly for a read operation, the contents of <b>EMACMIIDATA</b> are not valid until this bit is cleared.</p> <p>Value Description</p> <p>0 <b>EMACMIADDR</b> and <b>EMACMIIDATA</b> are available for reads and writes.</p> <p>1 Read or write access is in progress.</p> <p>The subsequent read or write operations should happen only after the previous operation is complete.</p> |

## Register 6: Ethernet MAC MII Data Register (EMACMIIDATA), offset 0x014

The **Ethernet MAC MII Data (EMACMIIDATA)** register holds data that is written to and read from the PHY register located at the address specified by the PLA and MII bit fields of the **Ethernet MAC MII Address (EMACMIADDR)** register.

## Register 7: Ethernet MAC Flow Control (EMACFLOWCTL), offset 0x018

The **Ethernet MAC Flow Control (EMACFLOWCTL)** register controls the generation and reception of the control (pause command) frames by the MAC's Flow control module. A write to a register with the FCBBPA (bit 0) set to 1 triggers the Flow Control block to generate a pause control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the pause time (PT) value from this register is used in the pause time field of the control frame. The FCBBPA bit is cleared by the hardware once the control frame is transferred onto the cable. The Host must make sure that the busy bit is clear before writing to the register.

| 0         | FCBBPA | RW   | 0     | <p>Flow Control Busy or Back-pressure Activate</p> <p>In the full-duplex mode, this bit should be read as 0x0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 0x1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 0x0. The <b>EMACFLOWCTL</b> register should not be written to until this bit is cleared.</p> <p>Value Description</p> <p>0 No effect</p> <p>1 In the full-duplex mode, a pause control frame is enabled. In half-duplex mode, a back-pressure function is enabled if the TFE bit is set.</p> |

## Register 8: Ethernet MAC VLAN Tag (EMACVLANTG), offset 0x01C

The **Ethernet MAC VLAN Tag (MACVLANTG)** register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with the value 0x8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes.

### Ethernet MAC VLAN Tag (EMACVLANTG)

Base 0x400E.C000

Offset 0x01C

Type RW, reset 0x0000.0000

A value of 1 in the <b>EMACVLANTHASH</b> register, corresponding to the index, indicates that the frame matched the VLAN hash table. | When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. |  |

The frames with matched VLAN tag are marked as matched.</p> <p>1 VLAN tag inverse matching is enabled. The frames that do not have matching VLAN tag are marked as matched.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 16        | ETV  | RW   | 0      | <p>Enable 12-Bit VLAN Tag Comparison</p> <p>Value Description</p> <p>0 All 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering.</p> <p>1 A 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag.</p> <p>Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering.</p>                                                                                                                                                                                                                                                                     |
| 15:0      | VL   | RW   | 0x0000 | <p>VLAN Tag Identifier for Receive Frames</p> <p>This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field:</p> <ul style="list-style-type: none"> <li>■ Bits [15:13]: User Priority</li> <li>■ Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)</li> <li>■ Bits[11:0]: VLAN tag's VLAN Identifier (VID) field</li> </ul> <p>When the ETV bit is set, only the VID field (Bits[11:0]) is used for comparison. If VL[11:0] is all zeros when the ETV is set, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88A8 as VLAN frames.</p> |

## Register 9: Ethernet MAC Status (EMACSTATUS), offset 0x024

The **Ethernet MAC Status (EMACSTATUS)** register gives the status of all main modules of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths.

### Ethernet MAC Status (EMACSTATUS)

Base 0x400E.C000

Offset 0x024

Type RO, reset 0x0000.0000

## Register 10: Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF), offset 0x028

This is the address through which the application writes or reads the remote wake-up frame filter registers. Note that to load values in the **Ethernet MAC Wake-up Frame Filter (EMACRWUFF)** register, the entire register must be written. The **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register is a pointer to eight wake-up frame filter registers. The **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register is loaded by sequentially loading the eight register values. Eight sequential writes to this address programs all of the remote wake-up frame filter registers. Similarly, eight sequential reads from the **EMACRWUFF** register reads all wake-up frame registers.

Upon reception, PWRDWN is self-cleared and the power-down mode is disabled. Software can also clear this bit before the expected magic packet or wake-up frame is received. The frames, received by the MAC after this bit is cleared, are forwarded to the application.</p> <p>Value Description</p> <p>0 Frames are forwarded to application.</p> <p>1 MAC receiver drops all received frames until it receives the expected magic packet or wake-up frame.</p> |

## Register 12: Ethernet MAC Raw Interrupt Status (EMACRIS), offset 0x038

The **Ethernet MAC Raw Interrupt Status (EMACRIS)** register identifies the events in the MAC that can generate interrupt.

### Ethernet MAC Raw Interrupt Status (EMACRIS)

Base 0x400E.C000

Offset 0x038

Type RO, reset 0x0000.0000

## Register 13: Ethernet MAC Interrupt Mask (EMACIM), offset 0x03C

The **Ethernet MAC Interrupt Mask (EMACIM)** Register bits enables the application to mask the interrupt signal caused by the corresponding event in the **Ethernet MAC Raw Interrupt Status (EMACRIS)** Register.

### Ethernet MAC Interrupt Mask (EMACIM)

Base 0x400E.C000

Offset 0x03C

Type RW, reset 0x0000.0000

**Register 14: Ethernet MAC Address 0 High (EMACADDR0H), offset 0x040**

The **Ethernet MAC Address 0 High (EMACADDR0H)** register holds the upper 16 bits of the first 6-byte MAC address of the station. The first (Destination Address) DA byte that is received on the MII interface corresponds to the least significant byte (Bits [7:0]) of the **MAC Address 0 Low Register (EMACADDR0L)** register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the **EMAC Address 0 (EMACADDR0x)** register [47:0] is compared with 0x665544332211.

**Ethernet MAC Address 0 High (EMACADDR0H)**

Base 0x400E.C000

|           |      |      |       | 0 When this bit is reset, the MAC Address2[47:0] is used to compare with the DA fields of the received frame.                                                                                                                                                                                                                                                                                                          |
|           |      |      |       | 1 When this bit is set, the MAC Address2[47:0] is used to compare with the SA fields of the received frame.                                                                                                                                                                                                                                                                                                            |
| 29:24     | MBC  | RW   | 0x0   | Mask Byte Control                                                                                                                                                                                                                                                                                                                                                                                                      |
|           |      |      |       | Mask control bits are provided for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows:                                                                                                                                                |
|           |      |      |       | <ul style="list-style-type: none"> <li>Bit 29: ADDRHI [15:8] of <b>EMACADDR2H</b> register</li> <li>Bit 28: ADDRHI [7:0] of <b>EMACADDR2H</b> register</li> <li>Bit 27: ADDRLO [31:24] of <b>EMACADDR2L</b> register</li> <li>Bit 26: ADDRLO [23:16] of <b>EMACADDR2L</b> register</li> <li>Bit 25: ADDRLO [15:8] of <b>EMACADDR2L</b> register</li> <li>Bit 24: ADDRLO [7:0] of <b>EMACADDR2L</b> register</li> </ul> |
|           |      |      |       | A group of addresses (known as group address filtering) can be filtered by masking one or more bytes of the address.                                                                                                                                                                                                                                                                                                   |

**Register 19: Ethernet MAC Address 2 Low (EMACADDR2L), offset 0x054**

The MAC Address2 Low register holds the lower 32 bits of the third 6-byte MAC address of the station.

Ethernet MAC Address 2 Low (EMACADDR2L)

Base 0x400E.C000  
Offset 0x054  
Type RW, reset 0xFFFF.FFFF

| 13:0      | WTO      | RW   | 0     | Watchdog Timeout                                                                                                                                                                                                                                                                                                |
|           |          |      |       | When the PWE bit in the <b>EMACWDOGTO</b> register is set and the WD bit of the <b>EMACCFG</b> register is clear, this field is used as a watchdog timeout value for a received frame. If the length of a received frame exceeds the value of this field, such frame is terminated and declared an error frame. |
|           |          |      |       | <b>Note:</b> When the PWE bit is set the value in this field should be more than 1,522 (0x05F2). Otherwise, valid, tagged IEEE 802.3-frames are declared as error frames and are dropped.                                                                                                                       |

**Register 23: Ethernet MAC MMC Control (EMACMMCCTRL), offset 0x100**

The MMC Control register establishes the operating mode of the management counters.

**Note:** The CNTRST bit has higher priority than the CNTPRST. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST is not set.

**Ethernet MAC MMC Control (EMACMMCCTRL)**

## Register 24: Ethernet MAC MMC Receive Raw Interrupt Status (EMACMMCRXRIS), offset 0x104

The **MAC MMC Receive Interrupt (EMACMMCRXRIS)** register maintains the interrupts that are generated when the following happens:

- Receive statistic counters reach half of their maximum values (0x8000.0000 for 32-bit counter and 0x8000 for 16-bit counter).
- Receive statistic counters cross their maximum values (0xFFFF.FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When the Counter Stop Rollover (CNTSTPRO bit) in the **MAC MMC Control (EMACMMCCTRL)** register is set, interrupts are set but the counter remains at all-ones. The **EMACMMCRXRIS** register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

## Register 25: Ethernet MAC MMC Transmit Raw Interrupt Status (EMACMMCTXRIS), offset 0x108

The **MAC MMC Transmit Interrupt (EMACMMCTXRIS)** register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000\_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF\_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the CNTSTPRO bit is set in the **MAC MMC Control (EMACMMCCTRL)** register, interrupts are set but the counter remains at all-ones. The **EMACMMCTXRIS** register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

## Register 28: Ethernet MAC Transmit Frame Count for Good and Bad Frames (EMACTXCNTGB), offset 0x118

The **MAC Transmit Frame Count for Good and Bad Frames (EMACTXCNTGB)** register maintains the number of good and bad frames transmitted, exclusive of retried frames.

**Note:** This counter is reset to all zeros by setting the CNTRST bit in the **Ethernet MAC MMC Control (EMACMMCCTRL)**, offset 0x100.

**Register 32: Ethernet MAC Receive Frame Count for Good and Bad Frames (EMACRXCNTGB), offset 0x180**

This register maintains the number of received good and bad frames.

**Note:** This counter is reset to all zeros by setting the CNTRST bit in the **Ethernet MAC MMC Control (EMACMMCCTRL)**, offset 0x100.

The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority, Bit 12 is the CFI/DEI, and Bits[11:0] are the VLAN tag's VID field.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Register 37: Ethernet MAC VLAN Hash Table (EMACVLANTHASH), offset 0x588**

The 16-bit hash table is used for group address filtering based on VLAN tag when the VTHM bit of the **EMACVLANTG** register is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (enabled by ETV in the **EMACVLANTG** register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the **EMACVLANTHASH** register. For example, a hash value of 0x8 selects bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper four bits from the value obtained in Step 2.

If the corresponding bit value of the register is 0x1, the frame is accepted. Otherwise, it is rejected.

## Register 39: Ethernet MAC Sub-Second Increment (EMACSUBSECINC), offset 0x704

In the Coarse Update mode (enabled by the TSCFUPDT bit in the **MAC Timestamp Control (EMACTIMSTCTRL)** register), the value in the **EMACSUBSECINC** register is added to the system time every clock cycle of slave clock reference, MOSC. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

### Ethernet MAC Sub-Second Increment (EMACSUBSECINC)

Base 0x400E.C000

Offset 0x704

Type RW, reset 0x0000.0000

| 7:0       | SSINC    | RW   | 0x0   | <p>Sub-second Increment Value</p> <p>The value programmed in this field is accumulated every clock cycle (MOSC) with the contents of the sub-second register. For example, when MOSC is 25 MHz (period is 40 ns), SSINC should be programmed with the value 40 (0x28) when the <b>Ethernet MAC System Time - Nanoseconds (EMACTIMNANO)</b> register has an accuracy of 1 ns (DGTLBIN bit is set in <b>EMACTIMSTCTRL</b>). When DGTLBIN bit is clear, the <b>EMACTIMNANO</b> register has a resolution of ~0.465ns. In this case, a value of 86 (0x56), that is derived by 40ns/0.465, should be programmed in the SSINC field.</p> |

**Register 40: Ethernet MAC System Time - Seconds (EMACTIMSEC), offset 0x708**

The **MAC System Time - Seconds (EMACTIMSEC)** register, along with the **MAC System Time - Nanoseconds (EMACTIMNANO)** register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies.

|           |      |      |       | <p>EN0PPS Output Frequency Control (PPSCTRL) or Command Control (PPSCMD)</p> <p>This bit field has two different functions depending on how the PPSEN0 bit is set.</p> <p>If the PPSEN0 bit is set to 0x0, this field functions as a PPS0 output frequency control (PPSCTRL), which controls the frequency of the output signal, EN0PPS. The default value of this field is 0x0 and the PPS output is one pulse every second.</p> <p>If the PPSEN0 bit is 0x1, this field functions as a flexible output command control for the EN0PPS signal. Programming the PPSCTRL bit field with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits are cleared automatically. Software should ensure that these bits are programmed only when they are "all-zeros."</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|           |      |      |       | <p>Value Description</p> <p>0x0 When the PPSEN0 bit = 0x0, the EN0PPS signal is 1 pulse of the PTP reference clock. every second.</p> <p>When the PPSEN0 bit = 0x1, this encoding indicates no command.</p> <p>0x1 When the PPSEN0 bit = 0x0, the binary rollover is 2 Hz, and the digital rollover is 1 Hz.</p> <p>When the PPSEN0 bit = 0x1, START single pulse. This command generates a single pulse rising at the start point defined in the <b>Ethernet MAC Target Time Second/Nanoseconds (EMACTARGX)</b> registers (MAC offsets 0x71C and 0x720) and a duration defined in the <b>Ethernet MAC PPS0 Width (EMACPPS0WIDTH)</b> register (offset 0x764).</p> <p>0x2 When the PPSEN0 bit = 0x0, the binary rollover is 4 Hz, and the digital rollover is 2 Hz.</p> <p>When the PPSEN0 bit = 0x1, START pulse train. This command generates the train of pulses rising at the start point defined in the <b>Ethernet MAC Target Time Second/Nanoseconds (EMACTARGX)</b> registers (MAC offsets 0x71C and 0x720) and repeated at an interval defined in the <b>Ethernet MAC PPS0 Width (EMACPPS0WIDTH)</b> register (offset 0x764). By default, the EN0PPS pulse train is free-running unless stopped by STOP pulse train at a time or STOP pulse train immediately command.</p> <p>0x3 When the PPSEN0 bit = 0x0, the binary rollover is 8 Hz, and the digital rollover is 4 Hz,</p> <p>When the PPSEN0 bit = 0x1, cancel START. This command cancels the START single pulse and START pulse train commands if the system time has not crossed the programmed start time.</p> <p>0x4 When the PPSEN0 bit = 0x0, the binary rollover is 16 Hz, and the digital rollover is 8 Hz.</p> <p>When the PPSEN0 bit = 0x1, STOP pulse train at time. This command stops the train of pulses initiated by the START pulse train command after the time programmed in the <b>Ethernet MAC Target Time Second/Nanoseconds (EMACTARGX)</b> registers (MAC offsets 0x71C and 0x720).</p> <p>0x5 When the PPSEN0 bit = 0x0, the binary rollover is 32 Hz, and the digital rollover is 16 Hz.</p> <p>When the PPSEN0 bit = 0x1, STOP pulse train immediately.</p> |

| 0xF                                                                                                                                                                            |      |      |       | When thePPSEN0 bit = 0x0, the binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz.<br>When the PPSEN0 bit = 0x1, this encoding is reserved.                                                                                                                                                                                         |
| Note that in the binary rollover mode, the EN0PPS signal has a duty cycle of 50 percent with these frequencies.                                                                |      |      |       |                                                                                                                                                                                                                                                                                                                                                       |
| In the digital rollover mode, the EN0PPS signal frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:   |      |      |       |                                                                                                                                                                                                                                                                                                                                                       |
| When PPCTRL = 0x1, EN0PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.                                                                                       |      |      |       |                                                                                                                                                                                                                                                                                                                                                       |
| When PPCTRL = 0x2, EN0PPS (2 Hz) is a sequence of:                                                                                                                             |      |      |       |                                                                                                                                                                                                                                                                                                                                                       |
| <ul style="list-style-type: none"> <li>■ One clock of 50 percent duty cycle and 537 ms period</li> <li>■ Second clock of 463 ms period (268 ms low and 195 ms high)</li> </ul> |      |      |       |                                                                                                                                                                                                                                                                                                                                                       |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|-------------|
|-----------|------|------|-------|-------------|

When PPSCTRL = 0x3, EN0PPS (4 Hz) is a sequence of:

- Three clocks of 50 percent duty cycle and 268 ms period
- Fourth clock of 195 ms period (134 ms low and 61 ms high)

This signaling behavior is because of the non-linear toggling of bits in the digital rollover mode in the **Ethernet MAC System Time - Nanoseconds (EMACTIMNANO)** register.

**Register 50: Ethernet MAC PPS0 Interval (EMACPPS0INTVL), offset 0x760**

The **MAC PPS0 Interval (EMACPPS0INTVL)** register contains the number of units of sub-second increment value between the rising edges of EN0PPS signal output.

**Note:** The PTP reference clock referred to below is MOSC clock in course update mode and in fine correction mode, is the clock tick at which the system time gets updated.

It is essential that all the PHY input clocks are present for the software reset completion. The time of the software reset operation depends on the frequency of the slowest active clock.</p> <p>Value Description</p> <p>0 Reset is completed. A value of 0 should be read before reprogramming any MAC registers after a reset</p> <p>1 MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the MAC clock domains.</p> |

Register 53: Ethernet MAC Transmit Poll Demand (EMACTXPOLL), offset 0xC04

The **MAC Transmit Poll Demand (EMACTXPOLL)** register enables the TX DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the TX DMA if it is in the suspend mode. The TX DMA can go into the SUSPEND mode because of an underflow error in a transmitted frame or the unavailability of descriptors owned by it. This Transmit Poll Demand command can be given at any time and the TX DMA resets this command when it again starts fetching the current descriptor from host memory.

Ethernet MAC Transmit Poll Demand (EMACTXPOLL)

| 31:0      | TPD  | WO   | 0x0   | <div>Transmit Poll Demand</div> <div>When these bits are written with any value, the DMA reads the current descriptor pointed to by the <b>MAC Current Host Transmit Descriptor (EMACHOSTXDESC)</b> register. If that descriptor is not available (owned by the Host), the transmission returns to the SUSPEND state and the TU bit of the <b>EMACDMARIS</b> is asserted. If the descriptor is available, the transmission resumes.</div> |

## Register 54: Ethernet MAC Receive Poll Demand (EMACRXPOLLD), offset 0xC08

The **Ethernet MAC Receive Poll Demand (EMACRXPOLLD)** register enables the RX DMA to check for new descriptors. This command is used to wake up the RX DMA from the SUSPEND state. The RX DMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

| 31:0      | RPD  | WO   | 0x0   | <p>Receive Poll Demand</p> <p>When these bits are written with any value, the DMA reads the current descriptor pointed to by <b>MAC Current Host Receive Descriptor (EMACHOSRXDESC)</b> register. If that descriptor is not available (owned by the Host), the reception returns to the SUSPEND state and the RU bit of <b>EMACDMARIS</b> is not asserted. If the descriptor is available, the RX DMA returns to the active state.</p> |

## Register 55: Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR), offset 0xC0C

The **Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR)** register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be word-aligned. The DMA internally converts it to a 32-bit aligned address by making the two least significant bits zero. Writing to this register is permitted only when the DMA receive transaction has stopped (SR = 0 in the **MAC DMA Operation Mode (EMACDMAOPMODE)** register). When stopped, this register must be written with a new descriptor list address before the receive Start command is given. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA uses the already existing descriptor address.

## Register 56: Ethernet MAC Transmit Descriptor List Address (EMACTXDLADDR), offset 0xC10

The **MAC Transmit Descriptor List Address (EMACTXDLADDR)** register points to the start of the transmit descriptor list. The descriptor lists reside in the host's physical memory space and must be word-aligned.

This register can only be written when the DMA transmit has stopped (ST = 0 in the **MAC DMA Operation Mode (EMACDMAOPMODE)** register). When the ST bit is set, the DMA takes the uses the newly programmed descriptor base address.

If this register is not changed when the ST bit is set to 0, then the DMA uses the already existing descriptor address.

**Register 57: Ethernet MAC DMA Interrupt Status (EMACDMARIS), offset 0xC14**

The **MAC DMA Interrupt Status (EMACDMARIS)** register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing a 1 to any bit in the lower half-word of this register clears the bit and writing a 0 has no effect. Status bits [16:0] can be masked by enabling the appropriate mask in the **MAC DMA Interrupt Mask Register (EMACDMAIM)** register.

When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor.</p> <p>Value Description</p> <p>0 Frame transmission completion event has not occurred.</p> <p>1 Frame transmission is complete.</p> <p>This bit is cleared by writing a 1 to it.</p>                                                                                                                     |

## Register 58: Ethernet MAC DMA Operation Mode (EMACDMAOPMODE), offset 0xC18

The **MAC DMA Operation Mode (EMACDMAOPMODE)** register establishes the Transmit and Receive operating modes and commands. This register should be the last register to be written as part of the DMA initialization.

### Ethernet MAC DMA Operation Mode (EMACDMAOPMODE)

Base 0x400E.C000

Offset 0xC18

Type RW, reset 0x0000.0000

| 1         | The MAC does not drop the frames which only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors only in the encapsulated payload. |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |       |             |   |                                                                                                   |   |                                                                                                                                                                                                                                                               |

| 13        | ST                                                                                                                                                                                                                                          | RW   | 0x0   | <p>Start or Stop Transmission Command</p> <p>When this bit is set, transmission is placed in the running state. The DMA attempts to acquire the descriptor from the Transmit Descriptor List. Descriptor acquisition is attempted from the current position in the list, which is the Transmit List Base Address set by <b>Transmit Descriptor List Address (EMACTXDLADDR)</b> register, or from the position retained when transmission was stopped previously.</p> <p>If the DMA does not own the current descriptor, transmission enters the suspended state and bit[2] (Transmit Buffer Unavailable, TU) of the <b>MAC DMA Raw Interrupt Status Register (EMACDMARIS)</b> is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting <b>EMACTXDLADDR</b>, then the DMA behavior is unpredictable.</p> <p>When this bit is cleared, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program <b>EMACTXDLADDR</b> with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>Transmission process is placed in the stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted.</td></tr><tr><td>1</td><td>Transmission is placed in the running state, and the DMA checks the transmit list at the current position for a frame to be transmitted.</td></tr></tbody></table> | Value | Description | 0 | Transmission process is placed in the stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. | 1 | Transmission is placed in the running state, and the DMA checks the transmit list at the current position for a frame to be transmitted. |

To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |   |                                                                                                                                                                                                                                             |   |                                                                                                                                          |
| 7         | FEF                                                                                                                                                                                                                                         | RW   | 0x0   | <p>Forward Error Frames</p> <p>When this bit is reset, the RX FIFO drops frames with error status (CRC error, collision error, MII_ER, giant frame, watchdog timeout, or overflow). However, if the start byte (write) pointer of a frame is already transferred to the RX controller side (in Threshold mode), then the frame is not dropped.</p> <p>When the FEF bit is set, all frames except runt error frames are forwarded to the DMA. If Bit 25, Receive Store and Forward (RSF), is set and the RX FIFO overflows when a partial frame is written, then the frame is dropped irrespective of the FEF bit setting. However, if the RSF is reset and the RX FIFO overflows when a partial frame is written, then a partial frame may be forwarded to the DMA.</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>The Receive FIFO drops frames with error status</td></tr><tr><td>1</td><td>All frames except runt error frames are forwarded to the DMA.</td></tr></tbody></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Value | Description | 0 | The Receive FIFO drops frames with error status                                                                                                                                                                                             | 1 | All frames except runt error frames are forwarded to the DMA.                                                                            |

| 1         | SR                                                                           | RW   | 0x0   | <p>Start or Stop Receive</p> <p>When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by the Receive Descriptor List Address Register (<b>EMACRXDLADDR</b>) or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and Bit 7 (Receive Buffer Unavailable, RU) of the MAC DMA Interrupt Status Register (<b>EMACDMARIS</b>) is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting <b>EMACRXDLADDR</b>, the DMA behavior is unpredictable.</p> <p>When this bit is cleared, the receive DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>The receive DMA operation is stopped after the transfer of the current frame</td></tr><tr><td>1</td><td>The Receive process is placed in the Running state.</td></tr></table> | Value | Description | 0 | The receive DMA operation is stopped after the transfer of the current frame | 1 | The Receive process is placed in the Running state. |

## Register 59: Ethernet MAC DMA Interrupt Mask Register (EMACDMAIM), offset 0xC1C

The Interrupt Enable register enables the interrupts reported by the MAC DMA Interrupt Status Register (**EMACDMARIS**). Setting a bit to 0x1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

### Ethernet MAC DMA Interrupt Mask Register (EMACDMAIM)

Base 0x400E.C000

Offset 0xC1C

Type RW, reset 0x0000.0000

## Register 60: Ethernet MAC Missed Frame and Buffer Overflow Counter (EMACMBOC), offset 0xC20

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counters. The counter is used for diagnostic purposes. The MISFRMCNT field indicates missed frames because of the host buffer being unavailable. The OVFFRMCNT field indicates missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

### Ethernet MAC Missed Frame and Buffer Overflow Counter (EMACMBOC)

## Register 67: Ethernet MAC Peripheral Configuration Register (EMACPC), offset 0xFC4

The **Ethernet MAC Peripheral Configuration Register (EMACPC)** register configures the MAC reset and interface parameters.

### Ethernet MAC Peripheral Configuration Register (EMACPC)

Base 0x400E.C000

Offset 0xFC4

Type RW, reset 0x0080.040E

## Register 68: Ethernet MAC Clock Configuration Register (EMACCC), offset 0xFC8

The following register is used to configure the clocks of the Ethernet Controller.

### Ethernet MAC Clock Configuration Register (EMACCC)

Base 0x400E.C000

Offset 0xFC8

Type RO, reset 0x0000.0000

#### Value Description

- |   |                                                                                                                       |
|---|-----------------------------------------------------------------------------------------------------------------------|
| 0 | An Ethernet PHY interrupt is suppressed and not sent to the interrupt controller.                                     |
| 1 | An Ethernet PHY interrupt is sent to the interrupt controller when the INT bit is set in the <b>EPHYRIS</b> register. |

## Register 71: Ethernet PHY Masked Interrupt Status and Clear (EPHYMISC), offset 0xFD8

The **Ethernet PHY Masked Interrupt Status and Clear (EPHYMISC)** register displays the masked interrupt status of the external Ethernet PHY attached to the MII/RMII interface and can be written to clear the **EPHYRIS** register.

This register is used for clearing the **EPHYRIS** register bits.

A write of 1 to a bit of this register clears the corresponding bit in the <b>EPHYRIS</b> register.</p> <p><b>Note:</b> The Ethernet MAC interrupt is an OR'd summary of both the masked <b>EMACRIS</b> register output and this register. When an Ethernet MAC interrupt is asserted, software must check both the <b>EMACRIS</b> and <b>EMACIM</b> registers along with this register.</p> |

## 24 Universal Serial Bus (USB) Controller

---

**Important:** The full USB chapter is under NDA. This chapter describes the module features at a high level. For a copy of the full NDA data sheet, follow the instructions in the *Non-Disclosure Agreement for the Tiva C Series TM4C129DNCZAD Microcontroller Data Sheet* (literature number [SPMS417](#)).

---

The TM4C129DNCZAD USB controller operates as a full-speed or low-speed function controller during point-to-point communications with USB Host, Device, or OTG functions. If the integrated ULPI interface is utilized, the USB can operate at high-speed. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. 16 endpoints including two hard-wired for control transfers (one endpoint for IN and one endpoint for OUT) plus 14 endpoints defined by firmware along with a dynamic sizable FIFO support multiple packet queueing. USB DMA access to the FIFO allows minimal interference from system software. Software-controlled connect and disconnect allows flexibility during USB device start-up. The controller complies with OTG Standard's Session Request Protocol (SRP) and Host Negotiation Protocol (HNP).

The TM4C129DNCZAD USB module has the following features:

- Complies with USB-IF (Implementer's Forum) certification standards
- USB 2.0 high-speed (480 Mbps) operation with the integrated ULPI interface communicating with an external PHY
- Link Power Management support which uses link-state awareness to reduce power usage
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- VBUS droop detection and interrupt
- Integrated USB DMA with bus master capability
  - Up to eight RX Endpoint channels and up to eight TX Endpoint channels are available.
  - Each channel can be separately programmed to operate in different modes
  - Incremental burst transfers of 4-, 8-, 16- or unspecified length supported

## 24.1 Block Diagram

Figure 24-1. USB Module Block Diagram

## 24.2 Signal Description

The following table lists the external signals of the USB controller and describes the function of each. Some USB controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these USB signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to choose the USB function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 788) to assign the USB signal to the specified GPIO port pin. The USB0VBUS and USB0ID signals are configured by clearing the appropriate DEN bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 741. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

**Note:** When used in OTG mode, USB0VBUS and USB0ID do not require any configuration as they are dedicated pins for the USB controller and directly connect to the USB connector's VBUS and ID signals. If the USB controller is used as either a dedicated Host or Device, the DEVMOD field in the **USB General-Purpose Control and Status (USBGPCS)** register can be used to connect the USB0VBUS and/or USB0ID inputs to fixed levels internally, freeing the PB0 and PB1 pins for GPIO use. Note that PB1 (USB0VBUS) is a 5-V tolerant signal as required. For proper self-powered Device operation, the VBUS value must still be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

The termination resistors for the USB PHY have been added internally, and thus there is no need for external resistors. For a device, there is a 1.5 KOhm pull-up on the D+ and for a host there are 15 KOhm pull-downs on both D+ and D-.

**Note:** Port pins PL6 and PL7 operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIO2R**, **GPIO4R**, **GPIO8R**, **GPIO12R**, **GPIOSLR**, and **GPIOODR**. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 741 and “Recommended GPIO Operating Characteristics” on page 1902 for more information.

Table 24-1. USB Signals (212BGA)

| Pin Name | Pin Number     | Pin Mux / Pin Assignment       | Pin Type | Buffer Type | Description                                                                                                                                                                                                                                                   |
|----------|----------------|--------------------------------|----------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USB0CLK  | B17            | PB3 (14)                       | O        | TTL         | 60-MHz clock to the external PHY.                                                                                                                                                                                                                             |
| USB0D0   | G16            | PL0 (14)                       | I/O      | TTL         | USB data 0.                                                                                                                                                                                                                                                   |
| USB0D1   | H19            | PL1 (14)                       | I/O      | TTL         | USB data 1.                                                                                                                                                                                                                                                   |
| USB0D2   | G18            | PL2 (14)                       | I/O      | TTL         | USB data 2.                                                                                                                                                                                                                                                   |
| USB0D3   | J18            | PL3 (14)                       | I/O      | TTL         | USB data 3.                                                                                                                                                                                                                                                   |
| USB0D4   | H18            | PL4 (14)                       | I/O      | TTL         | USB data 4.                                                                                                                                                                                                                                                   |
| USB0D5   | G19            | PL5 (14)                       | I/O      | TTL         | USB data 5.                                                                                                                                                                                                                                                   |
| USB0D6   | B12            | PP5 (14)                       | I/O      | TTL         | USB data 6.                                                                                                                                                                                                                                                   |
| USB0D7   | D8             | PP4 (14)                       | I/O      | TTL         | USB data 7.                                                                                                                                                                                                                                                   |
| USB0DIR  | C12            | PP3 (14)                       | O        | TTL         | Indicates that the external PHY is able to accept data from the USB controller.                                                                                                                                                                               |
| USB0DM   | B18            | PL7                            | I/O      | Analog      | Bidirectional differential data pin (D- per USB specification) for USB0.                                                                                                                                                                                      |
| USB0DP   | C18            | PL6                            | I/O      | Analog      | Bidirectional differential data pin (D+ per USB specification) for USB0.                                                                                                                                                                                      |
| USB0EPEN | V5<br>R7<br>B3 | PA6 (5)<br>PA7 (11)<br>PD6 (5) | O        | TTL         | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                              |
| USB0ID   | A16            | PB0                            | I        | Analog      | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| USB0NXT  | B13            | PP2 (14)                       | O        | TTL         | Asserted by the external PHY to throttle all data types.                                                                                                                                                                                                      |
| USB0PFLT | R7<br>B2       | PA7 (5)<br>PD7 (5)             | I        | TTL         | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                     |
| USB0STP  | A17            | PB2 (14)                       | O        | TTL         | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.                                                                                                                                                        |
| USB0VBUS | B16            | PB1                            | I/O      | Analog      | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                            |

## 24.3 Register Map

Table 24-2 on page 1713 lists the registers. All addresses given are relative to the USB base address of 0x4005.0000. Note that the USB controller clock must be enabled before the registers can be programmed (see page 397). There must be a delay of 3 system clocks after the USB module clock is enabled before any USB module registers are accessed.

**Note:** Descriptions for all these registers can be found in the NDA version of the data sheet.

**Table 24-2. List of Registers**

| Offset | Name           | Description                                            |
|--------|----------------|--------------------------------------------------------|
| 0x000  | USBFADDR       | USB Device Functional Address                          |
| 0x001  | USBPOWER       | USB Power                                              |
| 0x002  | USBTXIS        | USB Transmit Interrupt Status                          |
| 0x004  | USBRXIS        | USB Receive Interrupt Status                           |
| 0x006  | USBTXIE        | USB Transmit Interrupt Enable                          |
| 0x008  | USBRXIE        | USB Receive Interrupt Enable                           |
| 0x00A  | USBIS          | USB General Interrupt Status                           |
| 0x00B  | USBIE          | USB Interrupt Enable                                   |
| 0x00C  | USBFRAME       | USB Frame Value                                        |
| 0x00E  | USBEPIDX       | USB Endpoint Index                                     |
| 0x00F  | USBTTEST       | USB Test Mode                                          |
| 0x020  | USBFIFO0       | USB FIFO Endpoint 0                                    |
| 0x024  | USBFIFO1       | USB FIFO Endpoint 1                                    |
| 0x028  | USBFIFO2       | USB FIFO Endpoint 2                                    |
| 0x02C  | USBFIFO3       | USB FIFO Endpoint 3                                    |
| 0x030  | USBFIFO4       | USB FIFO Endpoint 4                                    |
| 0x034  | USBFIFO5       | USB FIFO Endpoint 5                                    |
| 0x038  | USBFIFO6       | USB FIFO Endpoint 6                                    |
| 0x03C  | USBFIFO7       | USB FIFO Endpoint 7                                    |
| 0x060  | USBDEVCTL      | USB Device Control                                     |
| 0x061  | USBCCONF       | USB Common Configuration                               |
| 0x062  | USBTXFIFOSZ    | USB Transmit Dynamic FIFO Sizing                       |
| 0x063  | USBRXFIFOSZ    | USB Receive Dynamic FIFO Sizing                        |
| 0x064  | USBTXFIFOADD   | USB Transmit FIFO Start Address                        |
| 0x066  | USBRXFIFOADD   | USB Receive FIFO Start Address                         |
| 0x070  | ULPIVBUSCTL    | USB ULPI VBUS Control                                  |
| 0x074  | ULPIREGDATA    | USB ULPI Register Data                                 |
| 0x075  | ULPIREGADDR    | USB ULPI Register Address                              |
| 0x076  | ULPIREGCTL     | USB ULPI Register Control                              |
| 0x078  | USBEPINFO      | USB Endpoint Information                               |
| 0x079  | USBRAMINFO     | USB RAM Information                                    |
| 0x07A  | USBCONTIM      | USB Connect Timing                                     |
| 0x07B  | USBVPLEN       | USB OTG VBUS Pulse Timing                              |
| 0x07C  | USBHSEOF       | USB High-Speed Last Transaction to End of Frame Timing |
| 0x07D  | USBFSEOF       | USB Full-Speed Last Transaction to End of Frame Timing |
| 0x07E  | USBLSEOF       | USB Low-Speed Last Transaction to End of Frame Timing  |
| 0x080  | USBTXFUNCADDR0 | USB Transmit Functional Address Endpoint 0             |
| 0x082  | USBTXHUBADDR0  | USB Transmit Hub Address Endpoint 0                    |
| 0x083  | USBTXHUBPORT0  | USB Transmit Hub Port Endpoint 0                       |
| 0x088  | USBTXFUNCADDR1 | USB Transmit Functional Address Endpoint 1             |

Table 24-2. List of Registers (*continued*)

| Offset | Name           | Description                                |
|--------|----------------|--------------------------------------------|
| 0x08A  | USBTXHUBADDR1  | USB Transmit Hub Address Endpoint 1        |
| 0x08B  | USBTXHUBPORT1  | USB Transmit Hub Port Endpoint 1           |
| 0x08C  | USBRXFUNCADDR1 | USB Receive Functional Address Endpoint 1  |
| 0x08E  | USBRXHUBADDR1  | USB Receive Hub Address Endpoint 1         |
| 0x08F  | USBRXHUBPORT1  | USB Receive Hub Port Endpoint 1            |
| 0x090  | USBTXFUNCADDR2 | USB Transmit Functional Address Endpoint 2 |

## 25 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result.

**Note:** Not all comparators have the option to drive an output pin. See “Signal Description” on page 1720 for more information.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board. In addition, the comparator can signal the application via interrupts or trigger the start of a sample sequence in the ADC. The interrupt generation and ADC triggering logic is separate and independent. This flexibility means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The TM4C129DNCZAD microcontroller provides three independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

## 25.1 Block Diagram

Figure 25-1. Analog Comparator Module Block Diagram

**Note:** This block diagram depicts the maximum number of analog comparators and comparator outputs for the family of microcontrollers; the number for this specific device may vary. See page 1733 for what is included on this device.

## 25.2 Signal Description

The following table lists the external signals of the Analog Comparators and describes the function of each. The Analog Comparator output signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the Analog Comparator signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to choose the Analog Comparator function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 788) to assign the Analog Comparator signal to the specified GPIO port pin. The positive and negative input signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 741.

Table 25-1. Analog Comparators Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                         |
|----------|------------|--------------------------|----------|-------------|-------------------------------------|
| C0+      | L2         | PC6                      | I        | Analog      | Analog comparator 0 positive input. |

Table 25-1. Analog Comparators Signals (212BGA) (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                         |
|----------|------------|--------------------------|----------|-------------|-------------------------------------|

## 25.3 Functional Description

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

$VIN- < VIN+, VOUT = 1$

$VIN- > VIN+, VOUT = 0$

As shown in Figure 25-2 on page 1721, the input source for VIN- is an external input, Cn-, where n is the analog comparator number. In addition to an external input, Cn+, input sources for VIN+ can be the C0+ or an internal reference, V<sub>IREF</sub>.

Figure 25-2. Structure of Comparator Unit

A comparator is configured through two status/control registers, **Analog Comparator Control (ACCTL)** and **Analog Comparator Status (ACSTAT)**. The internal reference is configured through one control register, **Analog Comparator Reference Voltage Control (ACREFCTL)**. Interrupt status and control are configured through three registers, **Analog Comparator Masked Interrupt Status (ACMIS)**, **Analog Comparator Raw Interrupt Status (ACRIS)**, and **Analog Comparator Interrupt Enable (ACINTEN)**.

Typically, the comparator output is used internally to generate an interrupt as controlled by the ISEN bit in the **ACCTL** register. The output may also be used to drive one of the external pins (Cno), or generate an analog-to-digital converter (ADC) trigger.

**Important:** The ASRCP bits in the **ACCTL** register must be set before using the analog comparators.

### 25.3.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 25-3 on page 1722. The internal reference is controlled by a single configuration register (**ACREFCTL**).

**Figure 25-3. Comparator Internal Reference Structure**

**Note:** In the figure above,  $N \cdot R$  represents a multiple of the  $R$  value that produces the results specified in Table 25-2 on page 1722.

The internal reference can be programmed in one of two modes (low range or high range) depending on the RNG bit in the **ACREFCTL** register. When RNG is clear, the internal reference is in high-range mode, and when RNG is set the internal reference is in low-range mode.

In each range, the internal reference,  $V_{IREF}$ , has 16 preprogrammed thresholds or step values. The threshold to be used to compare the external input voltage against is selected using the VREF field in the **ACREFCTL** register.

In the high-range mode, the  $V_{IREF}$  threshold voltages start at the ideal high-range starting voltage of  $V_{DDA}/4.2$  and increase in ideal constant voltage steps of  $V_{DDA}/29.4$ .

In the low-range mode, the  $V_{IREF}$  threshold voltages start at 0 V and increase in ideal constant voltage steps of  $V_{DDA}/22.12$ . The ideal  $V_{IREF}$  step voltages for each mode and their dependence on the RNG and VREF fields are summarized in Table 25-2.

**Table 25-2. Internal Reference Voltage and ACREFCTL Field Values**

| ACREFCTL Register |               | Output Reference Voltage Based on VREF Field Value                                                                  |
|-------------------|---------------|---------------------------------------------------------------------------------------------------------------------|
| EN Bit Value      | RNG Bit Value |                                                                                                                     |
| EN=0              | RNG=X         | 0 V (GND) for any value of VREF. It is recommended that RNG=1 and VREF=0 to minimize noise on the reference ground. |

**Table 25-2. Internal Reference Voltage and ACREFACTL Field Values (continued)**

| ACREFACTL Register |               | Output Reference Voltage Based on VREF Field Value                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EN Bit Value       | RNG Bit Value |                                                                                                                                                                                                                                                                                                                                                                                                      |
| EN=1               | RNG=0         | $V_{IREF}$ High Range: 16 voltage threshold values indexed by $VREF = 0x0 \dots 0xF$<br>Ideal starting voltage ( $VREF=0$ ): $V_{DDA} / 4.2$<br>Ideal step size: $V_{DDA} / 29.4$<br>Ideal $V_{IREF}$ threshold values: $V_{IREF}(VREF) = V_{DDA} / 4.2 + VREF * (V_{DDA} / 29.4)$ , for $VREF = 0x0 \dots 0xF$<br>For minimum and maximum $V_{IREF}$ threshold values, see Table 25-3 on page 1723. |
|                    | RNG=1         | $V_{IREF}$ Low Range: 16 voltage threshold values indexed by $VREF = 0x0 \dots 0xF$<br>Ideal starting voltage ( $VREF=0$ ): 0 V<br>Ideal step size: $V_{DDA} / 22.12$<br>Ideal $V_{IREF}$ threshold values: $V_{IREF}(VREF) = VREF * (V_{DDA} / 22.12)$ , for $VREF = 0x0 \dots 0xF$<br>For minimum and maximum $V_{IREF}$ threshold values, see Table 25-4 on page 1724.                            |

Note that the values shown in Table 25-2 are the ideal values of the  $V_{IREF}$  thresholds. These values actually vary between minimum and maximum values for each threshold step, depending on process and temperature. The minimum and maximum values for each step are given by:

- $V_{IREF}(VREF) [Min] = \text{Ideal } V_{IREF}(VREF) - (\text{Ideal Step size} - 2 \text{ mV}) / 2$
- $V_{IREF}(VREF) [Max] = \text{Ideal } V_{IREF}(VREF) + (\text{Ideal Step size} - 2 \text{ mV}) / 2$

Examples of minimum and maximum  $V_{IREF}$  values for  $V_{DDA} = 3.3V$  for high and low ranges, are shown in Table 25-3 and Table 25-4. Note that these examples are only valid for  $V_{DDA} = 3.3V$ ; values scale up and down with  $V_{DDA}$ .

**Table 25-3. Analog Comparator Voltage Reference Characteristics,  $V_{DDA} = 3.3V$ , EN= 1, and RNG = 0**

| VREF Value | $V_{IREF}$ Min | Ideal $V_{IREF}$ | $V_{IREF}$ Max | Unit |
|------------|----------------|------------------|----------------|------|

## 25.4 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator clock by writing a value of 0x0000.0001 to the **RCGCACMP** register in the System Control module (see page 400).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 386). To find out which GPIO ports to enable, refer to Table 29-5 on page 1887.
3. In the GPIO module, enable the GPIO port/pin associated with the input signals as GPIO inputs. To determine which GPIO to configure, see Table 29-4 on page 1873.
4. Configure the  $PMCn$  fields in the **GPIOPCTL** register to assign the analog comparator output signals to the appropriate pins (see page 788 and Table 29-5 on page 1887).
5. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
6. Configure the comparator to use the internal voltage reference and to *not* invert the output by writing the **ACCTLn** register with the value of 0x0000.040C.
7. Delay for 10  $\mu s$ .
8. Read the comparator output value by reading the **ACSTATn** register's OVAL value.

Change the level of the comparator negative input signal C- to see the OVAL value change.

## 25.5 Register Map

Table 25-5 on page 1725 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000. Note that the analog comparator clock must be enabled before the registers can be programmed (see page 400). There must be a delay of 3 system clocks after the analog comparator module clock is enabled before any analog comparator module registers are accessed.

**Table 25-5. Analog Comparators Register Map**

| Offset | Name     | Type | Reset       | Description                                 | See page |

## 25.6 Register Descriptions

The remainder of this section lists and describes the Analog Comparator registers, in numerical order by address offset.

## Register 1: Analog Comparator Masked Interrupt Status (ACMIS), offset 0x000

This register provides a summary of the interrupt status (masked) of the comparators.

### Analog Comparator Masked Interrupt Status (ACMIS)

Base 0x4003.C000

Offset 0x000

Type RW1C, reset 0x0000.0000

**Register 2: Analog Comparator Raw Interrupt Status (ACRIS), offset 0x004**

This register provides a summary of the interrupt status (raw) of the comparators. The bits in this register must be enabled to generate interrupts using the **ACINTEN** register.

**Analog Comparator Raw Interrupt Status (ACRIS)**

Base 0x4003.C000

## 26 Pulse Width Modulator (PWM)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

The TM4C129DNCZAD microcontroller contains one PWM module, with four PWM generator blocks and a control block, for a total of 8 PWM outputs. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that share the same timer and frequency and can either be programmed with independent actions or as a single pair of complementary signals with dead-band delays inserted. The output signals, `pwmA'` and `pwmB'`, of the PWM generation blocks are managed by the output control block before being passed to the device pins as `MnPWM0` and `MnPWM1` or `MnPWM2` and `MnPWM3`, and so on.

The TM4C129DNCZAD PWM module provides a great deal of flexibility and can generate simple PWM signals, such as those required by a simple charge pump as well as paired PWM signals with dead-band delays, such as those required by a half-H bridge driver. Three generator blocks can also generate the full six channels of gate controls required by a 3-phase inverter bridge.

Each PWM generator block has the following features:

- Four fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled
- One 16-bit counter
  - Runs in Down or Up/Down mode
  - Output frequency controlled by a 16-bit load value
  - Load value updates can be synchronized
  - Produces output signals at zero and load value
- Two PWM comparators
  - Comparator value updates can be synchronized
  - Produces output signals on match
- PWM signal generator
  - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
  - Produces two independent PWM signals
- Dead-band generator
  - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
  - Can be bypassed, leaving input PWM signals unmodified

- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal
- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Extended PWM synchronization of timer/comparator updates across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended PWM fault handling, with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

## **26.1 Block Diagram**

Figure 26-1 on page 1737 provides the TM4C129DNCZAD PWM module diagram and Figure 26-2 on page 1737 provides a more detailed diagram of a TM4C129DNCZAD PWM generator. The TM4C129DNCZAD controller contains four generator blocks that generate eight independent PWM signals or four paired PWM signals with dead-band delays inserted.

Figure 26-1. PWM Module Diagram

Figure 26-2. PWM Generator Block Diagram

## 26.2 Signal Description

The following table lists the external signals of the PWM module and describes the function of each. The PWM controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these PWM signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to choose the PWM function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 788) to assign the PWM signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 741.

## 26.3 Functional Description

### 26.3.1 Clock Configuration

The PWM has two clock source options:

- The System Clock
- A predivided System Clock

The clock source is selected by programming the USEPWM bit in the **PWM Clock Configuration (PWMCC)** register. The PWMDIV bitfield specifies the divisor of the System Clock that is used to create the PWM Clock.

### 26.3.2 PWM Timer

The timer in each PWM generator runs in one of two modes: Count-Down mode or Count-Up/Down mode. In Count-Down mode, the timer counts from the load value to zero, goes back to the load value, and continues counting down. In Count-Up/Down mode, the timer counts from zero up to the load value, back down to zero, back up to the load value, and so on. Generally, Count-Down mode is used for generating left- or right-aligned PWM signals, while the Count-Up/Down mode is used for generating center-aligned PWM signals.

The timers output three signals that are used in the PWM generation process: the direction signal (this is always Low in Count-Down mode, but alternates between Low and High in Count-Up/Down mode), a single-clock-cycle-width High pulse when the counter is zero, and a single-clock-cycle-width High pulse when the counter is equal to the load value. Note that in Count-Down mode, the zero pulse is immediately followed by the load pulse. In the figures in this chapter, these signals are labelled "dir," "zero," and "load."

### 26.3.3 PWM Comparators

Each PWM generator has two comparators that monitor the value of the counter; when either comparator matches the counter, they output a single-clock-cycle-width High pulse, labeled "cmpA" and "cmpB" in the figures in this chapter. When in Count-Up/Down mode, these comparators match both when counting up and when counting down, and thus are qualified by the counter direction signal. These qualified pulses are used in the PWM generation process. If either comparator match value is greater than the counter load value, then that comparator never outputs a High pulse.

Figure 26-3 on page 1740 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Down mode. Figure 26-4 on page 1740 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Up/Down mode. In these figures, the following definitions apply:

- LOAD is the value in the **PWMnLOAD** register
- COMPA is the value in the **PWMnCMPA** register
- COMPB is the value in the **PWMnCMPB** register
- 0 is the value zero
- load is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to the load value
- zero is the internal signal that has a single-clock-cycle-width High pulse when the counter is zero
- cmpA is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to COMPA
- cmpB is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to COMPB
- dir is the internal signal that indicates the count direction

**Figure 26-3. PWM Count-Down Mode****Figure 26-4. PWM Count-Up/Down Mode**

### 26.3.4 PWM Signal Generator

Each PWM generator takes the load, zero, cmpA, and cmpB pulses (qualified by the dir signal) and generates two internal PWM signals, pwmA and pwmB. In Count-Down mode, there are four events that can affect these signals: zero, load, match A down, and match B down. In Count-Up/Down mode, there are six events that can affect these signals: zero, load, match A down, match A up, match B down, and match B up. The match A or match B events are ignored when they coincide with the zero or load events. If the match A and match B events coincide, the first signal, pwmA, is generated based only on the match A event, and the second signal, pwmB, is generated based only on the match B event.

For each event, the effect on each output PWM signal is programmable: it can be left alone (ignoring the event), it can be toggled, it can be driven Low, or it can be driven High. These actions can be used to generate a pair of PWM signals of various positions and duty cycles, which do or do not overlap. Figure 26-5 on page 1741 shows the use of Count-Up/Down mode to generate a pair of center-aligned, overlapped PWM signals that have different duty cycles. This figure shows the pwmA and pwmB signals before they have passed through the dead-band generator.

**Figure 26-5. PWM Generation Example In Count-Up/Down Mode**

In this example, the first generator is set to drive High on match A up, drive Low on match A down, and ignore the other four events. The second generator is set to drive High on match B up, drive Low on match B down, and ignore the other four events. Changing the value of comparator A changes the duty cycle of the pwmA signal, and changing the value of comparator B changes the duty cycle of the pwmB signal.

### 26.3.5 Dead-Band Generator

The pwmA and pwmB signals produced by each PWM generator are passed to the dead-band generator. If the dead-band generator is disabled, the PWM signals simply pass through to the pwmA' and pwmB' signals unmodified. If the dead-band generator is enabled, the pwmB signal is lost and two PWM signals are generated based on the pwmA signal. The first output PWM signal, pwmA' is the pwmA signal with the rising edge delayed by a programmable amount. The second output PWM signal, pwmB', is the inversion of the pwmA signal with a programmable delay added between the falling edge of the pwmA signal and the rising edge of the pwmB' signal.

The resulting signals are a pair of active High signals where one is always High, except for a programmable amount of time at transitions where both are Low. These signals are therefore suitable for driving a half-H bridge, with the dead-band delays preventing shoot-through current from damaging the power electronics. Figure 26-6 on page 1741 shows the effect of the dead-band generator on the pwmA signal and the resulting pwmA' and pwmB' signals that are transmitted to the output control block.

**Figure 26-6. PWM Dead-Band Generator**

### 26.3.6 Interrupt/ADC-Trigger Selector

Each PWM generator also takes the same four (or six) counter events and uses them to generate an interrupt or an ADC trigger. Any of these events or a set of these events can be selected as a source for an interrupt; when any of the selected events occur, an interrupt is generated. Additionally, the same event, a different event, the same set of events, or a different set of events can be selected as a source for an ADC trigger; when any of these selected events occur, an ADC trigger pulse is generated. The selection of events allows the interrupt or ADC trigger to occur at a specific position

within the pwmA or pwmB signal. Note that interrupts and ADC triggers are based on the raw events; delays in the PWM signal edges caused by the dead-band generator are not taken into account.

### 26.3.7 Synchronization Methods

The PWM module provides four PWM generators, each providing two PWM outputs that may be used in a wide variety of applications. Generally speaking, the PWM is used in one of two categories of operation:

- **Unsynchronized.** The PWM generator and its two output signals are used alone, independent of other PWM generators.
- **Synchronized.** The PWM generator and its two outputs signals are used in conjunction with other PWM generators using a common, unified time base. If multiple PWM generators are configured with the same counter load value, synchronization can be used to guarantee that they also have the same count value (the PWM generators must be configured before they are synchronized). With this feature, more than two MnPWMn signals can be produced with a known relationship between the edges of those signals because the counters always have the same values. Other states in the module provide mechanisms to maintain the common time base and mutual synchronization.

The counter in a PWM generator can be reset to zero by writing the **PWM Time Base Sync (PWMSYNC)** register and setting the SYNCn bit associated with the generator. Multiple PWM generators can be synchronized together by setting all necessary SYNCn bits in one access. For example, setting the SYNC0 and SYNC1 bits in the **PWMSYNC** register causes the counters in PWM generators 0 and 1 to reset together.

Additional synchronization can occur between multiple PWM generators by updating register contents in one of the following three ways:

- **Immediately.** The write value has immediate effect, and the hardware reacts immediately.
- **Locally Synchronized.** The write value does not affect the logic until the counter reaches the value zero at the end of the PWM cycle. In this case, the effect of the write is deferred, providing a guaranteed defined behavior and preventing overly short or overly long output PWM pulses.
- **Globally Synchronized.** The write value does not affect the logic until two sequential events have occurred: (1) the Update mode for the generator function is programmed for global synchronization in the **PWMnCTL** register, and (2) the counter reaches zero at the end of the PWM cycle. In this case, the effect of the write is deferred until the end of the PWM cycle following the end of all updates. This mode allows multiple items in multiple PWM generators to be updated simultaneously without odd effects during the update; everything runs from the old values until a point at which they all run from the new values. The Update mode of the load and comparator match values can be individually configured in each PWM generator block. It typically makes sense to use the synchronous update mechanism across PWM generator blocks when the timers in those blocks are synchronized, although this is not required in order for this mechanism to function properly.

The following registers provide either local or global synchronization based on the state of various Update mode bits and fields in the **PWMnCTL** register (LOADUPD; CMPAUPD; CMPBUPD):

- Generator Registers: **PWMnLOAD**, **PWMnCMPA**, and **PWMnCMPB**

The following registers default to immediate update, but are provided with the optional functionality of synchronously updating rather than having all updates take immediate effect:

- Module-Level Register: **PWMENABLE** (based on the state of the ENUPDn bits in the PWMENUPD register).
- Generator Register: **PWMnGENA**, **PWMnGENB**, **PWMnDBCTL**, **PWMnDBRISE**, and **PWMnDBFALL** (based on the state of various Update mode bits and fields in the **PWMnCTL** register (GENAUPD; GENBUPD; DBCTLUPD; DBRISEUPD; DBFALLUPD)).

All other registers are considered statically provisioned for the execution of an application or are used dynamically for purposes unrelated to maintaining synchronization and therefore do not need synchronous update functionality.

### 26.3.8 Fault Conditions

A fault condition is one in which the controller must be signaled to stop normal PWM function and then set the MnPWMn signals to a safe state. Two basic situations cause fault conditions:

- The microcontroller is stalled and cannot perform the necessary computation in the time required for motion control
- An external error or event is detected

The PWM generator can use the following inputs to generate a fault condition, including:

- MnFAULTn pin assertion
- A stall of the controller generated by the debugger
- The trigger of an ADC digital comparator

Fault conditions are calculated on a per-PWM generator basis. Each PWM generator configures the necessary conditions to indicate a fault condition exists. This method allows the development of applications with dependent and independent control.

Four fault input pins (MnFAULTn) are available. These inputs may be used with circuits that generate an active High or active Low signal to indicate an error condition. A MnFAULTn pins may be individually programmed for the appropriate logic sense using the **PWMnFLTSEN** register.

The PWM generator's mode control, including fault condition handling, is provided in the **PWMnCTL** register. This register determines whether the input or a combination of MnFAULTn input signals and/or digital comparator triggers (as configured by the **PWMnFLTSRC0** and **PWMnFLTSRC1** registers) is used to generate a fault condition. The **PWMnCTL** register also selects whether the fault condition is maintained as long as the external condition lasts or if it is latched until the fault condition until cleared by software. Finally, this register also enables a counter that may be used to extend the period of a fault condition for external events to assure that the duration is a minimum length. The minimum fault period count is specified in the **PWMnMINFLTPER** register.

**Note:** When using an ADC digital comparator as a fault source, the LATCH and MINFLTPER bits in the **PWMnCTL** register should be set to 1 to ensure trigger assertions are captured.

Status regarding the specific fault cause is provided in the **PWMnFLTSTAT0** and **PWMnFLTSTAT1** registers. Note that the fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

PWM generator fault conditions may be promoted to a controller interrupt using the **PWMINTEN** register.

### 26.3.9 Output Control Block

The output control block takes care of the final conditioning of the pwmA' and pwmB' signals before they go to the pins as the MnPWMn signals. Via a single register, the **PWM Output Enable (PWENABLE)** register, the set of PWM signals that are actually enabled to the pins can be modified. This function can be used, for example, to perform commutation of a brushless DC motor with a single register write (and without modifying the individual PWM generators, which are modified by the feedback control loop). In addition, the updating of the bits in the **PWENABLE** register can be configured to be immediate or locally or globally synchronized to the next synchronous update using the **PWM Enable Update (PWMENUPE)** register.

During fault conditions, the PWM output signals, MnPWMn, usually must be driven to safe values so that external equipment may be safely controlled. The **PWMFAULT** register specifies whether during a fault condition, the generated signal continues to be passed driven or to an encoding specified in the **PWMFAULTVAL** register.

A final inversion can be applied to any of the MnPWMn signals, making them active Low instead of the default active High using the **PWM Output Inversion (PWMINVERT)**. The inversion is applied even if a value has been enabled in the **PWMFAULT** register and specified in the **PWMFAULTVAL** register. In other words, if a bit is set in the **PWMFAULT**, **PWMFAULTVAL**, and **PWMINVERT** registers, the output on the MnPWMn signal is 0, not 1 as specified in the **PWMFAULTVAL** register.

## 26.4 Initialization and Configuration

The following example shows how to initialize PWM Generator 0 with a 25-kHz frequency, a 25% duty cycle on the MnPWM0 pin, and a 75% duty cycle on the MnPWM1 pin. This example assumes the system clock is 20 MHz.

1. Enable the PWM clock by setting its corresponding bit in the **RCGCPWM** register in the System Control module (see page 401).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 386).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 29-4 on page 1873.
4. Configure the PMcN fields in the **GPIOCTL** register to assign the PWM signals to the appropriate pins (see page 788 and Table 29-5 on page 1887).
5. Configure the **PWM Clock Configuration (PWMCC)** register to use the PWM divide (USEPWMDIV) and set the divider (PWMDIV) to divide by 2 (0x0).
6. Configure the PWM generator for countdown mode with immediate updates to the parameters.
  - Write the **PWM0CTL** register with a value of 0x0000.0000.
  - Write the **PWM0GENA** register with a value of 0x0000.008C.
  - Write the **PWM0GENB** register with a value of 0x0000.080C.
7. Set the period. For a 25-KHz frequency, the period = 1/25,000, or 40 microseconds. The PWM clock source is 10 MHz; the system clock divided by 2. Thus there are 400 clock ticks per period. Use this value to set the **PWM0LOAD** register. In Count-Down mode, set the LOAD field in the **PWM0LOAD** register to the requested period minus one.

- Write the **PWM0LOAD** register with a value of 0x0000.018F.
- 8. Set the pulse width of the MnPWM0 pin for a 25% duty cycle.
  - Write the **PWM0CMPA** register with a value of 0x0000.012B.
- 9. Set the pulse width of the MnPWM1 pin for a 75% duty cycle.
  - Write the **PWM0CMPB** register with a value of 0x0000.0063.
- 10. Start the timers in PWM generator 0.
  - Write the **PWM0CTL** register with a value of 0x0000.0001.
- 11. Enable PWM outputs.
  - Write the **PWMENABLE** register with a value of 0x0000.0003.

## 26.5 Register Map

Table 26-2 on page 1745 lists the PWM registers. The offset listed is a hexadecimal increment to the register's address, relative to the PWM module's base address:

- PWM0: 0x4002.8000

Note that the PWM module clock must be enabled before the registers can be programmed. There must be a delay of 3 system clocks after the PWM module clock is enabled before any PWM module registers are accessed.

**Table 26-2. PWM Register Map**

| Offset | Name        | Type | Reset       | Description                       | See page |
|--------|-------------|------|-------------|-----------------------------------|----------|

## 26.6 Register Descriptions

The remainder of this section lists and describes the PWM registers, in numerical order by address offset.

**Register 1: PWM Master Control (PWMCTL), offset 0x000**

This register provides master control over the PWM generation blocks.

**PWM Master Control (PWMCTL)**

PWM0 base: 0x4002.8000

Offset 0x000

Type RW, reset 0x0000.0000

## Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004

This register provides a method to perform synchronization of the counters in the PWM generation blocks. Setting a bit in this register causes the specified counter to reset back to 0; setting multiple bits resets multiple counters simultaneously. The bits auto-clear after the reset has occurred; reading them back as zero indicates that the synchronization has completed.

### PWM Time Base Sync (PWMSYNC)

PWM0 base: 0x4002.8000

Offset 0x004

Type RW, reset 0x0000.0000

**Register 3: PWM Output Enable (PWMENABLE), offset 0x008**

This register provides a master control of which generated pwmA' and pwmB' signals are output to the MnPWMn pins. By disabling a PWM output, the generation process can continue (for example, when the time bases are synchronized) without driving PWM signals to the pins. When bits in this register are set, the corresponding pwmA' or pwmB' signal is passed through to the output stage. When bits are clear, the pwmA' or pwmB' signal is replaced by a zero value which is also passed to the output stage. The **PWMINVERT** register controls the output stage, so if the corresponding bit is set in that register, the value seen on the MnPWMn signal is inverted from what is configured by the bits in this register. Updates to the bits in this register can be immediate or locally or globally synchronized to the next synchronous update as controlled by the ENUPDn fields in the **PWMENUPD** register.

**Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C**

This register provides a master control of the polarity of the MnPWMn signals on the device pins. The pwmA' and pwmB' signals generated by the PWM generator are active High; but can be made active Low via this register. Disabled PWM channels are also passed through the output inverter (if so configured) so that inactive signals can be High. In addition, if the **PWMFAULT** register enables a specific value to be placed on the MnPWMn signals during a fault condition, that value is inverted if the corresponding bit in this register is set.

**Register 5: PWM Output Fault (PWMFAULT), offset 0x010**

This register controls the behavior of the MnPWMn outputs in the presence of fault conditions. Both the fault inputs (MnFAULTn pins and digital comparator outputs) and debug events are considered fault conditions. On a fault condition, each pwmA' or pwmB' signal can be passed through unmodified or driven to the value specified by the corresponding bit in the **PWMFAULTVAL** register. For outputs that are configured for pass-through, the debug event handling on the corresponding PWM generator also determines if the pwmA' or pwmB' signal continues to be generated.

Fault condition control occurs before the output inverter, so PWM signals driven to a specified value on fault are inverted if the channel is configured for inversion (therefore, the pin is driven to the logical complement of the specified value on a fault condition).

**Register 6: PWM Interrupt Enable (PWMINTEN), offset 0x014**

This register controls the global interrupt generation capabilities of the PWM module. The events that can cause an interrupt are the fault input and the individual interrupts from the PWM generators.

**Note:** The "n" in the INTFAULTn and INTPWMn bits in this register correspond to the PWM generators, not to the FAULTn signals.

**PWM Interrupt Enable (PWMINTEN)**

PWM0 base: 0x4002.8000

Offset 0x014

Type RW, reset 0x0000.0000

**Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018**

This register provides the current set of interrupt sources that are asserted, regardless of whether they are enabled to cause an interrupt to be asserted to the interrupt controller. The fault interrupt is asserted based on the fault condition source that is specified by the **PWMnCTL**, **PWMnFLTSRC0** and **PWMnFLTSRC1** registers. The fault interrupt is latched on detection and must be cleared through the **PWM Interrupt Status and Clear (PWMISC)** register. The actual value of the MnFAULTn signals can be observed using the **PWMSTATUS** register.

The PWM generator interrupts simply reflect the status of the PWM generators and are cleared via the interrupt status register in the PWM generator blocks. If a bit is set, the event is active; if a bit is clear the event is not active.

**PWM Raw Interrupt Status (PWMRIS)**

## Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C

This register provides a summary of the interrupt status of the individual PWM generator blocks. If a fault interrupt is set, the corresponding MnFAULTn input has caused an interrupt. For the fault interrupt, a write of 1 to that bit position clears the latched interrupt status. If an block interrupt bit is set, the corresponding generator block is asserting an interrupt. The individual interrupt status registers, **PWMnISC**, in each block must be consulted to determine the reason for the interrupt and used to clear the interrupt.

**Register 10: PWM Fault Condition Value (PWMFAULTVAL), offset 0x024**

This register specifies the output value driven on the MnPWMn signals during a fault condition if enabled by the corresponding bit in the **PWMFAULT** register. Note that if the corresponding bit in the **PWMINVERT** register is set, the output value is driven to the logical NOT of the bit value in this register.

**PWM Fault Condition Value (PWMFAULTVAL)**

PWM0 base: 0x4002.8000

Offset 0x024

Type RW, reset 0x0000.0000

**Register 11: PWM Enable Update (PWMENUPD), offset 0x028**

This register specifies when updates to the PWMnEN bit in the **PWMENABLE** register are performed. The PWMnEN bit enables the pwmA' or pwmB' output to be passed to the microcontroller's pin. Updates can be immediate or locally or globally synchronized to the next synchronous update.

**PWM Enable Update (PWMENUPD)**

PWM0 base: 0x4002.8000

Offset 0x028

Type RW, reset 0x0000.0000

**Register 12: PWM0 Control (PWM0CTL), offset 0x040****Register 13: PWM1 Control (PWM1CTL), offset 0x080****Register 14: PWM2 Control (PWM2CTL), offset 0x0C0****Register 15: PWM3 Control (PWM3CTL), offset 0x100**

These registers configure the PWM signal generation blocks (PWM0CTL controls the PWM generator 0 block, and so on). The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via these registers. The blocks produce the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

The PWM0 block produces the MnPWM0 and MnPWM1 outputs, the PWM1 block produces the MnPWM2 and MnPWM3 outputs, the PWM2 block produces the MnPWM4 and MnPWM5 outputs, and the PWM3 block produces the MnPWM6 and MnPWM7 outputs.

**PWMn Control (PWMnCTL)**

PWM0 base: 0x4002.8000

Offset 0x040

Type RW, reset 0x0000.0000

| 17        | MINFLTPER | RW   | 0     | <p>Minimum Fault Period</p> <p>This bit specifies that the PWM generator enables a one-shot counter to provide a minimum fault condition period.</p> <p>The timer begins counting on the rising edge of the fault condition to extend the condition for a minimum duration of the count value. The timer ignores the state of the fault condition while counting.</p> <p>The minimum fault delay is in effect only when the MINFLTPER bit is set. If a detected fault is in the process of being extended when the MINFLTPER bit is cleared, the fault condition extension is aborted.</p> <p>The delay time is specified by the <b>PWMnMINFLTPER</b> register MFP field value. The effect of this is to pulse stretch the fault condition input.</p> <p>The delay value is defined by the PWM clock period. Because the fault input is not synchronized to the PWM clock, the period of the time is <math>PWMClock * (MFP \text{ value} + 1)</math> or <math>PWMClock * (MFP \text{ value} + 2)</math>.</p> <p>The delay function makes sense only if the fault source is unlatched. A latched fault source makes the fault condition appear asserted until cleared by software and negates the utility of the extend feature. It applies to all fault condition sources as specified in the FLTSRC field.</p> <p>Value Description</p> <p>0 The FAULT input deassertion is unaffected.</p> <p>1 The <b>PWMnMINFLTPER</b> one-shot counter is active and extends the period of the fault condition to a minimum period.</p> <p><b>Note:</b> When using an ADC digital comparator as a fault source, the LATCH and MINFLTPER bits in the <b>PWMnCTL</b> register should be set to 1 to ensure trigger assertions are captured.</p> |
| 16        | FLTSRC    | RW   | 0     | <p>Fault Condition Source</p> <p>Value Description</p> <p>0 The Fault condition is determined by the Fault0 input.</p> <p>1 The Fault condition is determined by the configuration of the <b>PWMnFLTSRC0</b> and <b>PWMnFLTSRC1</b> registers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 0         | ENABLE | RW   | 0     | <p>PWM Block Enable</p> <p><b>Note:</b> Disabling the PWM by clearing the ENABLE bit does not clear the COUNT field of the <b>PWMnCOUNT</b> register. Before re-enabling the PWM (ENABLE = 0x1), the COUNT field should be cleared by resetting the PWM registers through the <b>SRPWM</b> register in the System Control Module.</p> <p>Value Description</p> <p>0 The entire PWM generation block is disabled and not clocked.</p> <p>1 The PWM generation block is enabled and produces PWM signals.</p> |

**Register 16: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044**

**Register 17: PWM1 Interrupt and Trigger Enable (PWM1INTEN), offset 0x084**

**Register 18: PWM2 Interrupt and Trigger Enable (PWM2INTEN), offset 0x0C4**

**Register 19: PWM3 Interrupt and Trigger Enable (PWM3INTEN), offset 0x104**

These registers control the interrupt and ADC trigger generation capabilities of the PWM generators (**PWM0INTEN** controls the PWM generator 0 block, and so on). The events that can cause an interrupt, or an ADC trigger are:

- The counter being equal to the load register
- The counter being equal to zero
- The counter being equal to the **PWMnCMPA** register while counting up
- The counter being equal to the **PWMnCMPA** register while counting down
- The counter being equal to the **PWMnCMB** register while counting up
- The counter being equal to the **PWMnCMB** register while counting down

Any combination of these events can generate either an interrupt or an ADC trigger, though no determination can be made as to the actual event that caused an ADC trigger if more than one is specified. The **PWMnRIS** register provides information about which events have caused raw interrupts.

#### PWMn Interrupt and Trigger Enable (PWMnINTEN)

PWM0 base: 0x4002.8000  
Offset 0x044  
Type RW, reset 0x0000.0000

**Register 20: PWM0 Raw Interrupt Status (PWM0RIS), offset 0x048****Register 21: PWM1 Raw Interrupt Status (PWM1RIS), offset 0x088****Register 22: PWM2 Raw Interrupt Status (PWM2RIS), offset 0x0C8****Register 23: PWM3 Raw Interrupt Status (PWM3RIS), offset 0x108**

These registers provide the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (**PWM0RIS** controls the PWM generator 0 block, and so on). If a bit is set, the event has occurred; if a bit is clear, the event has not occurred. Bits in this register are cleared by writing a 1 to the corresponding bit in the **PWMnISC** register.

**Register 24: PWM0 Interrupt Status and Clear (PWM0ISC), offset 0x04C****Register 25: PWM1 Interrupt Status and Clear (PWM1ISC), offset 0x08C****Register 26: PWM2 Interrupt Status and Clear (PWM2ISC), offset 0x0CC****Register 27: PWM3 Interrupt Status and Clear (PWM3ISC), offset 0x10C**

These registers provide the current set of interrupt sources that are asserted to the interrupt controller (**PWM0ISC** controls the PWM generator 0 block, and so on). A bit is set if the event has occurred and is enabled in the **PWMnINTEN** register; if a bit is clear, the event has not occurred or is not enabled. These are RW1C registers; writing a 1 to a bit position clears the corresponding interrupt reason.

**Note:** The interrupt status can only be cleared one PWM Clock cycle after the interrupt occurs. The larger the PWM Clock Divider (PWMDIV) value in **PWMCC** register, the longer the system delay is to clear the interrupt.

**Register 28: PWM0 Load (PWM0LOAD), offset 0x050****Register 29: PWM1 Load (PWM1LOAD), offset 0x090****Register 30: PWM2 Load (PWM2LOAD), offset 0x0D0****Register 31: PWM3 Load (PWM3LOAD), offset 0x110**

These registers contain the load value for the PWM counter (**PWM0LOAD** controls the PWM generator 0 block, and so on). Based on the counter mode configured by the **MODE** bit in the **PWMnCTL** register, this value is either loaded into the counter after it reaches zero or is the limit of up-counting after which the counter decrements back to zero. When this value matches the counter, a pulse is output which can be configured to drive the generation of the pwmA and/or pwmB signal (via the **PWMnGENA/PWMnGENB** register) or drive an interruptor ADC trigger (via the **PWMnINTEN** register).

If the Load Value Update mode is locally synchronized (based on the **LOADUPD** field encoding in the **PWMnCTL** register), the 16-bit **LOAD** value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1749). If this register is re-written before the actual update occurs, the previous value is never used and is lost.

**PWMn Load (PWMnLOAD)**

| 15:0      | COMPB    | RW   | 0x0000 | Comparator B Value<br>The value to be compared against the counter.                                                                                                                           |

**Register 44: PWM0 Generator A Control (PWM0GENA), offset 0x060****Register 45: PWM1 Generator A Control (PWM1GENA), offset 0x0A0****Register 46: PWM2 Generator A Control (PWM2GENA), offset 0x0E0****Register 47: PWM3 Generator A Control (PWM3GENA), offset 0x120**

These registers control the generation of the pwmA signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENA** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENA** register controls generation of the pwm0A signal; **PWM1GENA**, the pwm1A signal; **PWM2GENA**, the pwm2A signal; and **PWM3GENA**, the pwm3A signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare A action is taken and the compare B action is ignored.

If the Generator A update mode is immediate (based on the GENAUPD field encoding in the **PWMnCTL** register), the ACTCMPBD, ACTCMPBU, ACTCMPAD, ACTCMPAU, ACTLOAD, and ACTZERO values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1749). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**Register 48: PWM0 Generator B Control (PWM0GENB), offset 0x064****Register 49: PWM1 Generator B Control (PWM1GENB), offset 0x0A4****Register 50: PWM2 Generator B Control (PWM2GENB), offset 0x0E4****Register 51: PWM3 Generator B Control (PWM3GENB), offset 0x124**

These registers control the generation of the pwmB signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENB** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENB** register controls generation of the pwm0B signal; **PWM1GENB**, the pwm1B signal; **PWM2GENB**, the pwm2B signal; and **PWM3GENB**, the pwm3B signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare B action is taken and the compare A action is ignored.

If the Generator B update mode is immediate (based on the GENBUPD field encoding in the **PWMnCTL** register), the ACTCMPBD, ACTCMPBU, ACTCMPAD, ACTCMPAU, ACTLOAD, and ACTZERO values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1749). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**PWMn Generator B Control (PWMnGENB), offset 0x064**

**Register 52: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068****Register 53: PWM1 Dead-Band Control (PWM1DBCTL), offset 0x0A8****Register 54: PWM2 Dead-Band Control (PWM2DBCTL), offset 0x0E8****Register 55: PWM3 Dead-Band Control (PWM3DBCTL), offset 0x128**

The **PWMnDBCTL** register controls the dead-band generator, which produces the MnPWMn signals based on the pwmA and pwmB signals. When disabled, the pwmA signal passes through to the pwmA' signal and the pwmB signal passes through to the pwmB' signal. When dead-band control is enabled, the pwmB signal is ignored, the pwmA' signal is generated by delaying the rising edge(s) of the pwmA signal by the value in the **PWMnDBRISE** register (see page 1797), and the pwmB' signal is generated by inverting the pwmA signal and delaying the falling edge(s) of the pwmA signal by the value in the **PWMnDBFALL** register (see page 1798). The Output Control block outputs the pwm0A' signal on the MnPWM0 signal and the pwm0B' signal on the MnPWM1 signal. In a similar manner, MnPWM2 and MnPWM3 are produced from the pwm1A' and pwm1B' signals, MnPWM4 and MnPWM5 are produced from the pwm2A' and pwm2B' signals, and MnPWM6 and MnPWM7 are produced from the pwm3A' and pwm3B' signals.

If the Dead-Band Control mode is immediate (based on the DBCTLUPD field encoding in the **PWMnCTL** register), the ENABLE bit value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1749). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**Register 56: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C**

**Register 57: PWM1 Dead-Band Rising-Edge Delay (PWM1DBRISE), offset 0x0AC**

**Register 58: PWM2 Dead-Band Rising-Edge Delay (PWM2DBRISE), offset 0x0EC**

**Register 59: PWM3 Dead-Band Rising-Edge Delay (PWM3DBRISE), offset 0x12C**

The **PWMnDBRISE** register contains the number of clock cycles to delay the rising edge of the pwmA signal when generating the pwmA' signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a High pulse on the pwmA signal, the rising-edge delay consumes the entire High time of the signal, resulting in no High time on the output. Care must be taken to ensure that the pwmA High time always exceeds the rising-edge delay.

If the Dead-Band Rising-Edge Delay mode is immediate (based on the DBRISEUPD field encoding in the **PWMnCTL** register), the 12-bit RISEDELAY value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1749). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

| 11:0      | RISEDELAY | RW   | 0x000    | Dead-Band Rise Delay<br>The number of clock cycles to delay the rising edge of pwmA' after the rising edge of pwmA.                                                                           |

**Register 60: PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070**

**Register 61: PWM1 Dead-Band Falling-Edge-Delay (PWM1DBFALL), offset 0x0B0**

**Register 62: PWM2 Dead-Band Falling-Edge-Delay (PWM2DBFALL), offset 0x0F0**

**Register 63: PWM3 Dead-Band Falling-Edge-Delay (PWM3DBFALL), offset 0x130**

The **PWMnDBFALL** register contains the number of clock cycles to delay the rising edge of the pwmB' signal from the falling edge of the pwmA signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a Low pulse on the pwmA signal, the falling-edge delay consumes the entire Low time of the signal, resulting in no Low time on the output. Care must be taken to ensure that the pwmA Low time always exceeds the falling-edge delay.

If the Dead-Band Falling-Edge-Delay mode is immediate (based on the DBFALLUP field encoding in the **PWMnCTL** register), the 12-bit FALLDELAY value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1749). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**Register 64: PWM0 Fault Source 0 (PWM0FLTSRC0), offset 0x074****Register 65: PWM1 Fault Source 0 (PWM1FLTSRC0), offset 0x0B4****Register 66: PWM2 Fault Source 0 (PWM2FLTSRC0), offset 0x0F4****Register 67: PWM3 Fault Source 0 (PWM3FLTSRC0), offset 0x134**

This register specifies which fault pin inputs are used to generate a fault condition. Each bit in the following register indicates whether the corresponding fault pin is included in the fault condition. All enabled fault pins are ORed together to form the **PWMnFLTSRC0** portion of the fault condition. The **PWMnFLTSRC0** fault condition is then ORed with the **PWMnFLTSRC1** fault condition to generate the final fault condition for the PWM generator.

If the FLTSRC bit in the **PWMnCTL** register (see page 1774) is clear, only the Fault0 signal affects the fault condition generated. Otherwise, sources defined in **PWMnFLTSRC0** and **PWMnFLTSRC1** affect the fault condition generated.

**Register 72: PWM0 Minimum Fault Period (PWM0MINFLTPER), offset 0x07C**

**Register 73: PWM1 Minimum Fault Period (PWM1MINFLTPER), offset 0x0BC**

**Register 74: PWM2 Minimum Fault Period (PWM2MINFLTPER), offset 0x0FC**

**Register 75: PWM3 Minimum Fault Period (PWM3MINFLTPER), offset 0x13C**

If the MINFLTPER bit in the **PWMnCTL** register is set, this register specifies the 16-bit time-extension value to be used in extending the fault condition. The value is loaded into a 16-bit down counter, and the counter value is used to extend the fault condition. The fault condition is released in the clock immediately after the counter value reaches 0. The fault condition is asynchronous to the PWM clock; and the delay value is the product of the PWM clock period and the (MFP field value + 1) or (MFP field value + 2) depending on when the fault condition asserts with respect to the PWM clock. The counter decrements at the PWM clock rate, without pause or condition.

**Register 80: PWM0 Fault Status 0 (PWM0FLTSTAT0), offset 0x804****Register 81: PWM1 Fault Status 0 (PWM1FLTSTAT0), offset 0x884****Register 82: PWM2 Fault Status 0 (PWM2FLTSTAT0), offset 0x904****Register 83: PWM3 Fault Status 0 (PWM3FLTSTAT0), offset 0x984**

Along with the **PWMnFLTSTAT1** register, this register provides status regarding the fault condition inputs.

If the LATCH bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT0** register are read-only (RO) and provide the current state of the MnFAULTn inputs.

If the LATCH bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT0** register are read / write 1 to clear (RW1C) and provide a latched version of the MnFAULTn inputs. In this mode, the register bits are cleared by writing a 1 to a set bit. The MnFAULTn inputs are recorded after their sense is adjusted in the generator.

The contents of this register can only be written if the fault source extensions are enabled (the FLTSRC bit in the **PWMnCTL** register is set).

**Note:** The fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

**PWMn Fault Status 0 (PWMnFLTSTAT0)**

**Register 88: PWM Peripheral Properties (PWMPP), offset 0xFC0**

The **PWMPP** register provides information regarding the properties of the PWM module.

**PWM Peripheral Properties (PWMPP)**

PWM0 base: 0x4002.8000

Offset 0xFC0

Type RO, reset 0x0000.0344

## 27 Quadrature Encoder Interface (QEI)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, you can track the position, direction of rotation, and speed. In addition, a third channel, or index signal, can be used to reset the position counter.

The TM4C129DNCZAD quadrature encoder interface (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The TM4C129DNCZAD microcontroller includes one QEI module with the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
  - Index pulse
  - Velocity-timer expiration
  - Direction change
  - Quadrature error detection

### 27.1 Block Diagram

Figure 27-1 on page 1815 provides an internal block diagram of a TM4C129DNCZAD QEI module. The PhA and PhB inputs shown in this diagram are the internal signals that enter the Quadrature Encoder after the external signals, PhAn and PhBn, have passed through inversion and swapping logic shown in Figure 27-2 on page 1816. The QEI module has the option of inverting and/or swapping the incoming signals.

**Note:** Any references in this chapter to PhA and PhB refer to the internal PhA and PhB inputs that enter the Quadrature Encoder after the external signals, PhAn and PhBn, have passed through inversion and swapping logic that is enabled through the **QEI Control (QEICTL)** register.

Figure 27-1. QEI Block Diagram

Figure 27-2 on page 1816 shows the logic that is provided to allow the PhAn and PhBn signals to be inverted and/or swapped.

Figure 27-2. QEI Input Signal Logic

## 27.2 Signal Description

The following table lists the external signals of the QEI module and describes the function of each. The QEI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these QEI signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to choose the QEI function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 788) to assign the QEI signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 741.

Table 27-1. QEI Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description           |

## 27.3 Functional Description

The QEI module interprets the two-bit gray code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The position integrator and velocity capture can be independently enabled, though the position integrator must be enabled before the velocity capture can be enabled. The two phase signals,

PhAn and PhBn, can be swapped before being interpreted by the QEI module to change the meaning of forward and backward and to correct for miswiring of the system. Alternatively, the phase signals can be interpreted as a clock and direction signal as output by some encoders.

The QEI module input signals have a digital noise filter on them that can be enabled to prevent spurious operation. The noise filter requires that the inputs be stable for a specified number of consecutive clock cycles before updating the edge detector. The filter is enabled by the **FILTEN** bit in the **QEI Control (QEICTL)** register. The frequency of the input update is programmable using the **FILTCNT** bit field in the **QEICTL** register.

The QEI module supports two modes of signal operation: quadrature phase mode and clock/direction mode. In quadrature phase mode, the encoder produces two clocks that are 90 degrees out of phase; the edge relationship is used to determine the direction of rotation. In clock/direction mode, the encoder produces a clock signal to indicate steps and a direction signal to indicate the direction of rotation. This mode is determined by the **SIGMODE** bit of the **QEICTL** register (see page 1821).

When the QEI module is set to use the quadrature phase mode (**SIGMODE** bit is clear), the capture mode for the position integrator can be set to update the position counter on every edge of the PhA signal or to update on every edge of both PhA and PhB. Updating the position counter on every PhA and PhB edge provides more positional resolution at the cost of less range in the positional counter.

When edges on PhA lead edges on PhB, the position counter is incremented. When edges on PhB lead edges on PhA, the position counter is decremented. When a rising and falling edge pair is seen on one of the phases without any edges on the other, the direction of rotation has changed.

The positional counter is automatically reset on one of two conditions: sensing the index pulse or reaching the maximum position value. The reset mode is determined by the **RESMODE** bit of the **QEICTL** register.

When **RESMODE** is set, the positional counter is reset when the index pulse is sensed. This mode limits the positional counter to the values [0:N-1], where N is the number of phase edges in a full revolution of the encoder wheel. The **QEI Maximum Position (QEIMAXPOS)** register must be programmed with N-1 so that the reverse direction from position 0 can move the position counter to N-1. In this mode, the position register contains the absolute position of the encoder relative to the index (or home) position once an index pulse has been seen.

When **RESMODE** is clear, the positional counter is constrained to the range [0:M], where M is the programmable maximum value. The index pulse is ignored by the positional counter in this mode.

Velocity capture uses a configurable timer and a count register. The timer counts the number of phase edges (using the same configuration as for the position integrator) in a given time period. The edge count from the previous time period is available to the controller via the **QEI Velocity (QEISPEED)** register, while the edge count for the current time period is being accumulated in the **QEI Velocity Counter (QEICOUNT)** register. As soon as the current time period is complete, the total number of edges counted in that time period is made available in the **QEISPEED** register (overwriting the previous value), the **QEICOUNT** register is cleared, and counting commences on a new time period. The number of edges counted in a given time period is directly proportional to the velocity of the encoder.

Figure 27-3 on page 1818 shows how the TM4C129DNCZAD quadrature encoder converts the phase input signals into clock pulses, the direction signal, and how the velocity predivider operates (in Divide by 4 mode).

Figure 27-3. Quadrature Encoder and Velocity Predivider Operation

The period of the timer is configurable by specifying the load value for the timer in the **QEI Timer Load (QEILOAD)** register. When the timer reaches zero, an interrupt can be triggered, and the hardware reloads the timer with the **QEILOAD** value and continues to count down. At lower encoder speeds, a longer timer period is required to be able to capture enough edges to have a meaningful result. At higher encoder speeds, both a shorter timer period and/or the velocity predivider can be used.

The following equation converts the velocity counter value into an rpm value:

$$\text{rpm} = (\text{clock} * (2 \wedge \text{VELDIV}) * \text{SPEED} * 60) \div (\text{LOAD} * \text{ppr} * \text{edges})$$

where:

clock is the controller clock rate

ppr is the number of pulses per revolution of the physical encoder

edges is 2 or 4, based on the capture mode set in the **QEICTL** register (2 for CAPMODE clear and 4 for CAPMODE set)

For example, consider a motor running at 600 rpm. A 2048 pulse per revolution quadrature encoder is attached to the motor, producing 8192 phase edges per revolution. With a velocity predivider of  $\div 1$  (VELDIV is clear) and clocking on both PhA and PhB edges, this results in 81,920 pulses per second (the motor turns 10 times per second). If the timer were clocked at 10,000 Hz, and the load value was 2,500 ( $\frac{1}{4}$  of a second), it would count 20,480 pulses per update. Using the above equation:

$$\text{rpm} = (10000 * 1 * 20480 * 60) \div (2500 * 2048 * 4) = 600 \text{ rpm}$$

Now, consider that the motor is sped up to 3000 rpm. This results in 409,600 pulses per second, or 102,400 every  $\frac{1}{4}$  of a second. Again, the above equation gives:

$$\text{rpm} = (10000 * 1 * 102400 * 60) \div (2500 * 2048 * 4) = 3000 \text{ rpm}$$

Care must be taken when evaluating this equation because intermediate values may exceed the capacity of a 32-bit integer. In the above examples, the clock is 10,000 and the divider is 2,500; both could be predivided by 100 (at compile time if they are constants) and therefore be 100 and 25. In fact, if they were compile-time constants, they could also be reduced to a simple multiply by 4, cancelled by the  $\div 4$  for the edge-count factor.

**Important:** Reducing constant factors at compile time is the best way to control the intermediate values of this equation and reduce the processing requirement of computing this equation.

The division can be avoided by selecting a timer load value such that the divisor is a power of 2; a simple shift can therefore be done in place of the division. For encoders with a power of 2 pulses per revolution, the load value can be a power of 2. For other encoders, a load value must be selected such that the product is very close to a power of 2. For example, a 100 pulse-per-revolution encoder

could use a load value of 82, resulting in 32,800 as the divisor, which is 0.09% above  $2^{14}$ . In this case a shift by 15 would be an adequate approximation of the divide in most cases. If absolute accuracy were required, the microcontroller's divide instruction could be used.

The QEI module can produce a controller interrupt on several events: phase error, direction change, reception of the index pulse, and expiration of the velocity timer. Standard masking, raw interrupt status, interrupt status, and interrupt clear capabilities are provided.

## 27.4 Initialization and Configuration

The following example shows how to configure the Quadrature Encoder module to read back an absolute position:

1. Enable the QEI clock using the **RCGCQEI** register in the System Control module (see page 402).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 386).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 29-4 on page 1873.
4. Configure the PMCN fields in the **GPIOPCTL** register to assign the QEI signals to the appropriate pins (see page 788 and Table 29-5 on page 1887).
5. Configure the quadrature encoder to capture edges on both signals and maintain an absolute position by resetting on index pulses. A 1000-line encoder with four edges per line, results in 4000 pulses per revolution; therefore, set the maximum position to 3999 (0xF9F) as the count is zero-based.
  - Write the **QEICTL** register with the value of 0x0000.0018.
  - Write the **QEIMAXPOS** register with the value of 0x0000.0F9F.
6. Enable the quadrature encoder by setting bit 0 of the **QEICTL** register.
 

**Note:** Once the QEI module has been enabled by setting the ENABLE bit in the **QEICTL** register, it cannot be disabled. The only way to clear the ENABLE bit is to reset the module using the **Quadrature Encoder Interface Software Reset (SRQEI)** register.
7. Delay until the encoder position is required.
8. Read the encoder position by reading the **QEI Position (QEIPOS)** register value.

## 27.5 Register Map

Table 27-2 on page 1820 lists the QEI registers. The offset listed is a hexadecimal increment to the register's address, relative to the module's base address:

- QEIO: 0x4002.C000

Note that the QEI module clock must be enabled before the registers can be programmed (see page 402). There must be a delay of 3 system clocks after the QEI module clock is enabled before any QEI module registers are accessed.

**Table 27-2. QEI Register Map**

| Offset | Name      | Type | Reset       | Description                    | See page |

## 27.6 Register Descriptions

The remainder of this section lists and describes the QEI registers, in numerical order by address offset.

**Register 1: QEI Control (QEICTL), offset 0x000**

This register contains the configuration of the QEI module. Separate enables are provided for the quadrature encoder and the velocity capture blocks; the quadrature encoder must be enabled in order to capture the velocity, but the velocity does not need to be captured in applications that do not need it. The phase signal interpretation, phase swap, Position Update mode, Position Reset mode, and velocity predivider are all set via this register.

Register 3: QEI Position (QEIPOS), offset 0x008

This register contains the current value of the position integrator. The value is updated by the status of the QEI phase inputs and can be set to a specific value by writing to it.

QEI Position (QEIPOS)

QEIO base: 0x4002.C000  
Offset 0x008  
Type RW, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset       | Description                                                                        |
|-----------|----------|------|-------------|------------------------------------------------------------------------------------|
| 31:0      | POSITION | RW   | 0x0000.0000 | Current Position Integrator Value<br>The current value of the position integrator. |

Register 4: QEI Maximum Position (QEIMAXPOS), offset 0x00C

This register contains the maximum value of the position integrator. When moving forward, the position register resets to zero when it increments past this value. When moving in reverse, the position register resets to this value when it decrements from zero.

QEI Maximum Position (QEIMAXPOS)

QEIO base: 0x4002.C000  
Offset 0x00C  
Type RW, reset 0x0000.0000

| Bit/Field | Name   | Type | Reset       | Description                                                                        |

**Register 5: QEI Timer Load (QEILOAD), offset 0x010**

This register contains the load value for the velocity timer. Because this value is loaded into the timer on the clock cycle after the timer is zero, this value should be one less than the number of clocks in the desired period. So, for example, to have 2000 decimal clocks per timer period, this register should contain 1999 decimal.

**QEI Timer Load (QEILOAD)**

QEIO base: 0x4002.C000

Offset 0x010

| 31:0      | TIME | RO   | 0x0000.0000 | Velocity Timer Current Value<br>The current value of the velocity timer. |

**Register 7: QEI Velocity Counter (QEICOUNT), offset 0x018**

This register contains the running count of velocity pulses for the current time period. Because this count is a running total, the time period to which it applies cannot be known with precision (that is, a read of this register does not necessarily correspond to the time returned by the **QEITIME** register because there is a small window of time between the two reads, during which either value may have changed). The **QEISPEED** register should be used to determine the actual encoder velocity; this register is provided for information purposes only. This counter does not increment when the VELEN bit in the **QEICTL** register is clear.

## Register 10: QEI Raw Interrupt Status (QEIRIS), offset 0x024

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (configured through the **QEINTEN** register). If a bit is set, the latched event has occurred; if a bit is clear, the event in question has not occurred.

### QEI Raw Interrupt Status (QEIRIS)

|           |          |      |       | This bit is cleared by writing a 1 to the INTINDEX bit in the <b>QEISC</b> register. |

**Register 11: QEI Interrupt Status and Clear (QEISC), offset 0x028**

This register provides the current set of interrupt sources that are asserted to the controller. If a bit is set, the latched event has occurred and is enabled to generate an interrupt; if a bit is clear the event in question has not occurred or is not enabled to generate an interrupt. This register is RW1C; writing a 1 to a bit position clears the bit and the corresponding interrupt reason.

**QEI Interrupt Status and Clear (QEISC)**

QEIO base: 0x4002.C000

Offset 0x028

## 28 Pin Diagram

The TM4C129DNCZAD microcontroller pin diagram is shown below.

Each GPIO signal is identified by its GPIO port unless it defaults to an alternate function on reset. In this case, the GPIO port name is followed by the default alternate function. To see a complete list of possible functions for each pin, see Table 29-5 on page 1887.

### Figure 28-1. 212-Ball BGA Package Pin Diagram (Top View)

## 29 Signal Tables

The following tables list the signals available for each pin. Signals are configured as GPIOs on reset, except for those noted below. Use the **GPIOAMSEL** register (see page 787) to select analog mode. For a GPIO pin to be used for an alternate digital function, the corresponding bit in the **GPIOAFSEL** register (see page 771) must be set. Further pin muxing options are provided through the PMCx bit field in the **GPIOPCTL** register (see page 788), which selects one of several available peripheral functions for that GPIO.

**Important:** All GPIO pins are configured as GPIOs by default with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 29-1. GPIO Pins With Default Alternate Functions**

| GPIO Pin | Default State     | GPIOAFSEL Bit | GPIOPCTL PMCx Bit Field |
|----------|-------------------|---------------|-------------------------|
| PA[1:0]  | UART0             | 0             | 0x1                     |
| PA[5:2]  | SSI0              | 0             | 0x1                     |
| PB[3:2]  | I <sup>2</sup> C0 | 0             | 0x1                     |
| PC[3:0]  | JTAG/SWD          | 1             | 0x3                     |

Table 29-2 on page 1839 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Each possible alternate analog and digital function is listed for each pin.

Table 29-3 on page 1857 lists the signals in alphabetical order by signal name. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed. The "Pin Mux" column indicates the GPIO and the encoding needed in the PMCx bit field in the **GPIOPCTL** register.

Table 29-4 on page 1873 groups the signals by functionality, except for GPIOs. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed.

Table 29-5 on page 1887 lists the GPIO pins and their analog and digital alternate functions. The AINx analog signals are not 5-V tolerant and go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 3.3-V tolerant and are connected directly to their circuitry (C0-, C0+, C1-, C1+, C2-, C2+, USB0VBUS, USB0ID). These signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. The digital signals are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIODEN** registers and configuring the PMCx bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Table 29-6 on page 1892 lists the signals based on number of possible pin assignments. This table can be used to plan how to configure the pins for a particular functionality. Application Note AN01274 Configuring Tiva™ C Series Microcontrollers with Pin Multiplexing provides an overview of the pin muxing implementation, an explanation of how a system designer defines a pin configuration, and examples of the pin configuration process.

**Note:** All digital inputs are Schmitt triggered.

## 29.1 Signals by Pin Number

Table 29-2. Signals by Pin Number

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description                                                                                                                                      |
|------------|-----------|----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| A1         | GND       | -        | Power       | Ground reference for logic and I/O pins.                                                                                                         |
| A2         | GND       | -        | Power       | Ground reference for logic and I/O pins.                                                                                                         |
| A4         | PD4       | I/O      | TTL         | GPIO port D bit 4.                                                                                                                               |
|            | AIN7      | I        | Analog      | Analog-to-digital converter input 7.                                                                                                             |
|            | SSI1XDAT2 | I/O      | TTL         | SSI Module 1 Bi-directional Data Pin 2.                                                                                                          |
|            | T3CCP0    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 0.                                                                                                         |
|            | U2Rx      | I        | TTL         | UART module 2 receive.                                                                                                                           |
| A5         | PE4       | I/O      | TTL         | GPIO port E bit 4.                                                                                                                               |
|            | AIN9      | I        | Analog      | Analog-to-digital converter input 9.                                                                                                             |
|            | SSI1XDAT0 | I/O      | TTL         | SSI Module 1 Bi-directional Data Pin 0 (SSI1TX in Legacy SSI Mode).                                                                              |
|            | U1RI      | I        | TTL         | UART module 1 Ring Indicator modem status input signal.                                                                                          |
| A7         | PE6       | I/O      | TTL         | GPIO port E bit 6.                                                                                                                               |
|            | AIN20     | I        | Analog      | Analog-to-digital converter input 20.                                                                                                            |
|            | I2C9SCL   | I/O      | OD          | I <sup>2</sup> C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | U0CTS     | I        | TTL         | UART module 0 Clear To Send modem flow control input signal.                                                                                     |

| A13        | PQ4       | I/O      | TTL         | GPIO port Q bit 4.                                                                                                                               |
|            | DIVSCLK   | O        | TTL         | An optionally divided reference clock output based on a selected clock source. Note that this signal is not synchronized to the System Clock.    |
|            | U1Rx      | I        | TTL         | UART module 1 receive.                                                                                                                           |
| A14        | PS3       | I/O      | TTL         | GPIO port S bit 3.                                                                                                                               |
|            | M0FAULT3  | I        | TTL         | Motion Control Module 0 PWM Fault 3.                                                                                                             |
|            | T3CCP1    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 1.                                                                                                         |

Table 29-2. Signals by Pin Number (*continued*)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description                                                                                                                                                                                                                                                   |
|------------|-----------|----------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A16        | PB0       | I/O      | TTL         | GPIO port B bit 0.                                                                                                                                                                                                                                            |
|            | CAN1Rx    | I        | TTL         | CAN module 1 receive.                                                                                                                                                                                                                                         |
|            | I2C5SCL   | I/O      | OD          | I <sup>2</sup> C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                              |
|            | T4CCP0    | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 0.                                                                                                                                                                                                                      |
|            | U1Rx      | I        | TTL         | UART module 1 receive.                                                                                                                                                                                                                                        |
|            | USB0ID    | I        | Analog      | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| A17        | PB2       | I/O      | TTL         | GPIO port B bit 2.                                                                                                                                                                                                                                            |
|            | EN0MDC    | O        | TTL         | Ethernet 0 Management Data Clock.                                                                                                                                                                                                                             |
|            | EPI0S27   | I/O      | TTL         | EPI module 0 signal 27.                                                                                                                                                                                                                                       |
|            | I2C0SCL   | I/O      | OD          | I <sup>2</sup> C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                              |
|            | T5CCP0    | I/O      | TTL         | 16/32-Bit Timer 5 Capture/Compare/PWM 0.                                                                                                                                                                                                                      |
|            | USB0STP   | O        | TTL         | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.                                                                                                                                                        |
| A18        | GND       | -        | Power       | Ground reference for logic and I/O pins.                                                                                                                                                                                                                      |
| A19        | GND       | -        | Power       | Ground reference for logic and I/O pins.                                                                                                                                                                                                                      |
| B1         | GND       | -        | Power       | Ground reference for logic and I/O pins.                                                                                                                                                                                                                      |
| B2         | PD7       | I/O      | TTL         | GPIO port D bit 7.                                                                                                                                                                                                                                            |
|            | AIN4      | I        | Analog      | Analog-to-digital converter input 4.                                                                                                                                                                                                                          |
|            | NMI       | I        | TTL         | Non-maskable interrupt.                                                                                                                                                                                                                                       |
|            | SSI2XDAT2 | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 2.                                                                                                                                                                                                                       |
|            | T4CCP1    | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 1.                                                                                                                                                                                                                      |
|            | U2CTS     | I        | TTL         | UART module 2 Clear To Send modem flow control input signal.                                                                                                                                                                                                  |
|            | USB0PFLT  | I        | TTL         | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                     |
| B3         | PD6       | I/O      | TTL         | GPIO port D bit 6.                                                                                                                                                                                                                                            |
|            | AIN5      | I        | Analog      | Analog-to-digital converter input 5.                                                                                                                                                                                                                          |
|            | SSI2XDAT3 | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 3.                                                                                                                                                                                                                       |
|            | T4CCP0    | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 0.                                                                                                                                                                                                                      |
|            | U2RTS     | O        | TTL         | UART module 2 Request to Send modem flow control output line.                                                                                                                                                                                                 |
|            | USB0EPEN  | O        | TTL         | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                              |

| E7         | PJ1       | I/O      | TTL         | GPIO port J bit 1.                                                                                                                                                                                                                                                                                |
|            | U3Tx      | O        | TTL         | UART module 3 transmit.                                                                                                                                                                                                                                                                           |
| E10        | VDDC      | -        | Power       | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 30-15 on page 1913 . |

Table 29-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description                                                                                                                                                                                                                                                                                                                                                           |
|------------|----------|----------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E13        | NC       | -        | -           | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                                                                                                                          |
| E17        | PJ5      | I/O      | TTL         | GPIO port J bit 5.                                                                                                                                                                                                                                                                                                                                                    |
|            | U3CTS    | I        | TTL         | UART module 3 Clear To Send modem flow control input signal.                                                                                                                                                                                                                                                                                                          |
| E18        | PT2      | I/O      | TTL         | GPIO port T bit 2.                                                                                                                                                                                                                                                                                                                                                    |
|            | CAN1Rx   | I        | TTL         | CAN module 1 receive.                                                                                                                                                                                                                                                                                                                                                 |
|            | T7CCP0   | I/O      | TTL         | 16/32-Bit Timer 7 Capture/Compare/PWM 0.                                                                                                                                                                                                                                                                                                                              |
| E19        | OSC0     | I        | Analog      | Main oscillator crystal input or an external clock reference input.                                                                                                                                                                                                                                                                                                   |
| F1         | PB7      | I/O      | TTL         | GPIO port B bit 7.                                                                                                                                                                                                                                                                                                                                                    |
|            | I2C6SDA  | I/O      | OD          | I <sup>2</sup> C module 6 data.                                                                                                                                                                                                                                                                                                                                       |
|            | T6CCP1   | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 1.                                                                                                                                                                                                                                                                                                                              |
| F2         | PB6      | I/O      | TTL         | GPIO port B bit 6.                                                                                                                                                                                                                                                                                                                                                    |
|            | I2C6SCL  | I/O      | OD          | I <sup>2</sup> C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                                                                                                                                      |
|            | T6CCP0   | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 0.                                                                                                                                                                                                                                                                                                                              |
| F3         | VDDA     | -        | Power       | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in , regardless of system implementation.                                                     |
| F4         | VREFA+   | -        | Analog      | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value . The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 30-44 on page 1935. |
| F10        | GND      | -        | Power       | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                                                                                                              |

|            | AIN0     | I        | Analog      | Analog-to-digital converter input 0.                                                                                                                                                                                                                                                                                                                                  |
|            | U1DTR    | O        | TTL         | UART module 1 Data Terminal Ready modem status input signal.                                                                                                                                                                                                                                                                                                          |
| G4         | GNDA     | -        | Power       | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.                                                                                                                                                                     |

Table 29-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|-----------|----------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| G5         | VREFA-    | -        | Analog      | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 30-44 on page 1935. |
| G10        | VDD       | -        | Power       | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| H11        | GND       | -        | Power       | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| H12        | GND       | -        | Power       | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Table 29-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description                                                                                                                                                                                                                                                                                       |
|------------|----------|----------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| H16        | VDDC     | -        | Power       | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 30-15 on page 1913 . |
| H17        | PJ2      | I/O      | TTL         | GPIO port J bit 2.                                                                                                                                                                                                                                                                                |
|            | U2RTS    | O        | TTL         | UART module 2 Request to Send modem flow control output line.                                                                                                                                                                                                                                     |
| H18        | PL4      | I/O      | TTL         | GPIO port L bit 4.                                                                                                                                                                                                                                                                                |
|            | EPI0S26  | I/O      | TTL         | EPI module 0 signal 26.                                                                                                                                                                                                                                                                           |
|            | T0CCP0   | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 0.                                                                                                                                                                                                                                                          |
|            | USB0D4   | I/O      | TTL         | USB data 4.                                                                                                                                                                                                                                                                                       |
| H19        | PL1      | I/O      | TTL         | GPIO port L bit 1.                                                                                                                                                                                                                                                                                |
|            | EPI0S17  | I/O      | TTL         | EPI module 0 signal 17.                                                                                                                                                                                                                                                                           |
|            | I2C2SCL  | I/O      | OD          | I <sup>2</sup> C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                                                                  |
|            | PhA0     | I        | TTL         | QEI module 0 phase A.                                                                                                                                                                                                                                                                             |
|            | USB0D1   | I/O      | TTL         | USB data 1.                                                                                                                                                                                                                                                                                       |

|            | I2C2SDA     | I/O      | OD          | I <sup>2</sup> C module 2 data.                                                                                                                                               |
|            | SSI2XDAT2   | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 2.                                                                                                                                       |
| M17        | HIB         | O        | TTL         | An output that indicates the processor is in Hibernate mode.                                                                                                                  |
| M18        | PM4         | I/O      | TTL         | GPIO port M bit 4.                                                                                                                                                            |
|            | EN0RREF_CLK | I/O      | TTL         | Ethernet 0 Reference Clock.                                                                                                                                                   |
|            | T4CCP0      | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 0.                                                                                                                                      |
|            | TMPR3       | I/O      | TTL         | Tamper signal 3.                                                                                                                                                              |
|            | U0CTS       | I        | TTL         | UART module 0 Clear To Send modem flow control input signal.                                                                                                                  |

Table 29-2. Signals by Pin Number (*continued*)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description                                                                                                                                      |
|------------|----------|----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| N1         | PJ6      | I/O      | TTL         | GPIO port J bit 6.                                                                                                                               |
|            | U4RTS    | O        | TTL         | UART module 4 Request to Send modem flow control output line.                                                                                    |
| N2         | PR2      | I/O      | TTL         | GPIO port R bit 2.                                                                                                                               |
|            | I2C2SCL  | I/O      | OD          | I <sup>2</sup> C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0PWM2   | O        | TTL         | Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1.                                                            |
| N4         | PR1      | I/O      | TTL         | GPIO port R bit 1.                                                                                                                               |
|            | I2C1SDA  | I/O      | OD          | I <sup>2</sup> C module 1 data.                                                                                                                  |
|            | M0PWM1   | O        | TTL         | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.                                                            |
|            | U4Rx     | I        | TTL         | UART module 4 receive.                                                                                                                           |
| N5         | PR0      | I/O      | TTL         | GPIO port R bit 0.                                                                                                                               |
|            | I2C1SCL  | I/O      | OD          | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0PWM0   | O        | TTL         | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.                                                            |
|            | U4Tx     | O        | TTL         | UART module 4 transmit.                                                                                                                          |
| N10        | GND      | -        | Power       | Ground reference for logic and I/O pins.                                                                                                         |
| N15        | PG0      | I/O      | TTL         | GPIO port G bit 0.                                                                                                                               |
|            | EPI0S11  | I/O      | TTL         | EPI module 0 signal 11.                                                                                                                          |
|            | I2C1SCL  | I/O      | OD          | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0PWM4   | O        | TTL         | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.                                                            |
| N16        | VDD      | -        | Power       | Positive supply for I/O and some logic.                                                                                                          |
| N18        | PM7      | I/O      | TTL         | GPIO port M bit 7.                                                                                                                               |

|            | U0DSR    | I        | TTL         | UART module 0 Data Set Ready modem output control line.                                                                                          |
| P2         | PR5      | I/O      | TTL         | GPIO port R bit 5.                                                                                                                               |
|            | I2C3SDA  | I/O      | OD          | I <sup>2</sup> C module 3 data.                                                                                                                  |
|            | M0PWM5   | O        | TTL         | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.                                                            |
|            | T0CCP1   | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 1.                                                                                                         |
|            | U1Rx     | I        | TTL         | UART module 1 receive.                                                                                                                           |

Table 29-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description                                                                                                                                                                      |
|------------|-----------|----------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| P3         | PR4       | I/O      | TTL         | GPIO port R bit 4.                                                                                                                                                               |
|            | I2C3SCL   | I/O      | OD          | I <sup>2</sup> C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                 |
|            | M0PWM4    | O        | TTL         | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.                                                                                            |
|            | T0CCP0    | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 0.                                                                                                                                         |
| P4         | PH0       | I/O      | TTL         | GPIO port H bit 0.                                                                                                                                                               |
|            | EPI0S0    | I/O      | TTL         | EPI module 0 signal 0.                                                                                                                                                           |
|            | U0RTS     | O        | TTL         | UART module 0 Request to Send modem flow control output signal.                                                                                                                  |
| P10        | VDD       | -        | Power       | Positive supply for I/O and some logic.                                                                                                                                          |
| P16        | GND       | -        | Power       | Ground reference for logic and I/O pins.                                                                                                                                         |
| P17        | VDD       | -        | Power       | Positive supply for I/O and some logic.                                                                                                                                          |
| P18        | RST       | I        | TTL         | System reset input.                                                                                                                                                              |
| P19        | VBAT      | -        | Power       | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply. |
| R1         | PH2       | I/O      | TTL         | GPIO port H bit 2.                                                                                                                                                               |
|            | EPI0S2    | I/O      | TTL         | EPI module 0 signal 2.                                                                                                                                                           |
|            | U0DCD     | I        | TTL         | UART module 0 Data Carrier Detect modem status input signal.                                                                                                                     |
| R2         | PH1       | I/O      | TTL         | GPIO port H bit 1.                                                                                                                                                               |
|            | EPI0S1    | I/O      | TTL         | EPI module 0 signal 1.                                                                                                                                                           |
|            | U0CTS     | I        | TTL         | UART module 0 Clear To Send modem flow control input signal.                                                                                                                     |
| R3         | PH4       | I/O      | TTL         | GPIO port H bit 4.                                                                                                                                                               |
|            | U0DTR     | O        | TTL         | UART module 0 Data Terminal Ready modem status input signal.                                                                                                                     |
| R7         | PA7       | I/O      | TTL         | GPIO port A bit 7.                                                                                                                                                               |
|            | EPI0S9    | I/O      | TTL         | EPI module 0 signal 9.                                                                                                                                                           |
|            | I2C6SDA   | I/O      | OD          | I <sup>2</sup> C module 6 data.                                                                                                                                                  |
|            | SSI0XDAT3 | I/O      | TTL         | SSI Module 0 Bi-directional Data Pin 3.                                                                                                                                          |
|            | T3CCP1    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 1.                                                                                                                                         |
|            | U2Tx      | O        | TTL         | UART module 2 transmit.                                                                                                                                                          |
|            | USB0EPEN  | O        | TTL         | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                 |
|            | USB0PFLT  | I        | TTL         | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                        |
| R10        | PR7       | I/O      | TTL         | GPIO port R bit 7.                                                                                                                                                               |
|            | EN0TXEN   | O        | TTL         | Ethernet 0 Transmit Enable.                                                                                                                                                      |
|            | I2C4SDA   | I/O      | OD          | I <sup>2</sup> C module 4 data.                                                                                                                                                  |
|            | M0PWM7    | O        | TTL         | Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3.                                                                                            |
|            | T1CCP1    | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 1.                                                                                                                                         |
| R13        | PS7       | I/O      | TTL         | GPIO port S bit 7.                                                                                                                                                               |
|            | EN0RXDV   | I        | TTL         | Ethernet 0 Receive Data Valid.                                                                                                                                                   |
|            | T5CCP1    | I/O      | TTL         | 16/32-Bit Timer 5 Capture/Compare/PWM 1.                                                                                                                                         |

Table 29-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description                                                                                                                                                                                                                                      |
|------------|----------|----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R17        | GND      | -        | Power       | Ground reference for logic and I/O pins.                                                                                                                                                                                                         |
| R18        | GNDX     | -        | Power       | GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
| T1         | PH3      | I/O      | TTL         | GPIO port H bit 3.                                                                                                                                                                                                                               |
|            | EPI0S3   | I/O      | TTL         | EPI module 0 signal 3.                                                                                                                                                                                                                           |
|            | U0DSR    | I        | TTL         | UART module 0 Data Set Ready modem output control line.                                                                                                                                                                                          |
| T2         | PH5      | I/O      | TTL         | GPIO port H bit 5.                                                                                                                                                                                                                               |
|            | U0RI     | I        | TTL         | UART module 0 Ring Indicator modem status input signal.                                                                                                                                                                                          |
| T6         | PA2      | I/O      | TTL         | GPIO port A bit 2.                                                                                                                                                                                                                               |
|            | I2C8SCL  | I/O      | OD          | I <sup>2</sup> C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                 |
|            | SSI0Clk  | I/O      | TTL         | SSI module 0 clock                                                                                                                                                                                                                               |
|            | T1CCP0   | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 0.                                                                                                                                                                                                         |
|            | U4Rx     | I        | TTL         | UART module 4 receive.                                                                                                                                                                                                                           |
| T7         | PF3      | I/O      | TTL         | GPIO port F bit 3.                                                                                                                                                                                                                               |
|            | EN0MDIO  | I/O      | TTL         | Ethernet 0 Management Data Input/Output signal.                                                                                                                                                                                                  |
|            | M0PWM3   | O        | TTL         | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.                                                                                                                                                            |
|            | SSI3Clk  | I/O      | TTL         | SSI module 3 clock.                                                                                                                                                                                                                              |
|            | TRCLK    | O        | TTL         | Trace clock.                                                                                                                                                                                                                                     |
| T8         | PF6      | I/O      | TTL         | GPIO port F bit 6.                                                                                                                                                                                                                               |
| T12        | PN6      | I/O      | TTL         | GPIO port N bit 6.                                                                                                                                                                                                                               |
|            | EN0TXER  | O        | TTL         | Ethernet 0 transmit error.                                                                                                                                                                                                                       |
|            | U4RTS    | O        | TTL         | UART module 4 Request to Send modem flow control output line.                                                                                                                                                                                    |
| T13        | PS5      | I/O      | TTL         | GPIO port S bit 5.                                                                                                                                                                                                                               |
|            | EN0TXD1  | O        | TTL         | Ethernet 0 Transmit Data 1.                                                                                                                                                                                                                      |

Table 29-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description                                                                                                                                      |
|------------|-----------|----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| U5         | PA3       | I/O      | TTL         | GPIO port A bit 3.                                                                                                                               |
|            | I2C8SDA   | I/O      | OD          | I <sup>2</sup> C module 8 data.                                                                                                                  |
|            | SSI0Fss   | I/O      | TTL         | SSI module 0 frame signal                                                                                                                        |
|            | T1CCP1    | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 1.                                                                                                         |
|            | U4Tx      | O        | TTL         | UART module 4 transmit.                                                                                                                          |
| U6         | PF0       | I/O      | TTL         | GPIO port F bit 0.                                                                                                                               |
|            | M0PWM0    | O        | TTL         | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.                                                            |
|            | SSI3XDAT1 | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode).                                                                              |
|            | TRD2      | O        | TTL         | Trace data 2.                                                                                                                                    |
| U8         | PF7       | I/O      | TTL         | GPIO port F bit 7.                                                                                                                               |
| U10        | PS6       | I/O      | TTL         | GPIO port S bit 6.                                                                                                                               |
|            | EN0RXER   | I        | TTL         | Ethernet 0 Receive Error.                                                                                                                        |
|            | IDX0      | I        | TTL         | QEI module 0 index.                                                                                                                              |
|            | T5CCP0    | I/O      | TTL         | 16/32-Bit Timer 5 Capture/Compare/PWM 0.                                                                                                         |
| U12        | PN7       | I/O      | TTL         | GPIO port N bit 7.                                                                                                                               |
|            | U1RTS     | O        | TTL         | UART module 1 Request to Send modem flow control output line.                                                                                    |
|            | U4CTS     | I        | TTL         | UART module 4 Clear To Send modem flow control input signal.                                                                                     |
| U14        | PG7       | I/O      | TTL         | GPIO port G bit 7.                                                                                                                               |
|            | EN0RXDV   | I        | TTL         | Ethernet 0 Receive Data Valid.                                                                                                                   |
|            | I2C4SDA   | I/O      | OD          | I <sup>2</sup> C module 4 data.                                                                                                                  |
|            | SSI2Clk   | I/O      | TTL         | SSI module 2 clock.                                                                                                                              |
| U15        | PQ6       | I/O      | TTL         | GPIO port Q bit 6.                                                                                                                               |
|            | EN0RXD1   | I        | TTL         | Ethernet 0 Receive Data 1.                                                                                                                       |
|            | U1DTR     | O        | TTL         | UART module 1 Data Terminal Ready modem status input signal.                                                                                     |
| U18        | WAKE      | I        | TTL         | An external input that brings the processor out of Hibernate mode when asserted.                                                                 |
| U19        | PK4       | I/O      | TTL         | GPIO port K bit 4.                                                                                                                               |
|            | EN0INTRN  | I        | TTL         | Ethernet 0 Interrupt from the Ethernet PHY.                                                                                                      |
|            | EN0RXD3   | I        | TTL         | Ethernet 0 Receive Data 3.                                                                                                                       |
|            | EPI0S32   | I/O      | TTL         | EPI module 0 signal 32.                                                                                                                          |
|            | I2C3SCL   | I/O      | OD          | I <sup>2</sup> C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0PWM6    | O        | TTL         | Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3.                                                            |
| V1         | GND       | -        | Power       | Ground reference for logic and I/O pins.                                                                                                         |
| V2         | PH7       | I/O      | TTL         | GPIO port H bit 7.                                                                                                                               |
|            | U5Tx      | O        | TTL         | UART module 5 transmit.                                                                                                                          |
|            | U7Tx      | O        | TTL         | UART module 7 transmit.                                                                                                                          |

Table 29-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description                                                                                                                                      |
|------------|-----------|----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| V3         | PA0       | I/O      | TTL         | GPIO port A bit 0.                                                                                                                               |
|            | CAN0RX    | I        | TTL         | CAN module 0 receive.                                                                                                                            |
|            | I2C9SCL   | I/O      | OD          | I <sup>2</sup> C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | T0CCP0    | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 0.                                                                                                         |
|            | U0RX      | I        | TTL         | UART module 0 receive.                                                                                                                           |
| V4         | PA4       | I/O      | TTL         | GPIO port A bit 4.                                                                                                                               |
|            | I2C7SCL   | I/O      | OD          | I <sup>2</sup> C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | SSI0XDAT0 | I/O      | TTL         | SSI Module 0 Bi-directional Data Pin 0 (SSI0TX in Legacy SSI Mode).                                                                              |
|            | T2CCP0    | I/O      | TTL         | 16/32-Bit Timer 2 Capture/Compare/PWM 0.                                                                                                         |
|            | U3RX      | I        | TTL         | UART module 3 receive.                                                                                                                           |
| V5         | PA6       | I/O      | TTL         | GPIO port A bit 6.                                                                                                                               |
|            | EN0RXCK   | I        | TTL         | Ethernet 0 Receive Clock.                                                                                                                        |
|            | EPI0S8    | I/O      | TTL         | EPI module 0 signal 8.                                                                                                                           |
|            | I2C6SCL   | I/O      | OD          | I <sup>2</sup> C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | SSI0XDAT2 | I/O      | TTL         | SSI Module 0 Bi-directional Data Pin 2.                                                                                                          |
|            | T3CCP0    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 0.                                                                                                         |
|            | U2RX      | I        | TTL         | UART module 2 receive.                                                                                                                           |
|            | USB0EPEN  | O        | TTL         | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                 |
| V6         | PF1       | I/O      | TTL         | GPIO port F bit 1.                                                                                                                               |
|            | M0PWM1    | O        | TTL         | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.                                                            |
|            | SSI3XDAT0 | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode).                                                                              |
|            | TRD1      | O        | TTL         | Trace data 1.                                                                                                                                    |
| V7         | PF4       | I/O      | TTL         | GPIO port F bit 4.                                                                                                                               |
|            | M0FAULT0  | I        | TTL         | Motion Control Module 0 PWM Fault 0.                                                                                                             |
|            | SSI3XDAT2 | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 2.                                                                                                          |
|            | TRD3      | O        | TTL         | Trace data 3.                                                                                                                                    |
| V8         | PR3       | I/O      | TTL         | GPIO port R bit 3.                                                                                                                               |
|            | I2C2SDA   | I/O      | OD          | I <sup>2</sup> C module 2 data.                                                                                                                  |
|            | M0PWM3    | O        | TTL         | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.                                                            |
| V9         | PS4       | I/O      | TTL         | GPIO port S bit 4.                                                                                                                               |
|            | EN0TXD0   | O        | TTL         | Ethernet 0 Transmit Data 0.                                                                                                                      |
|            | PhA0      | I        | TTL         | QEI module 0 phase A.                                                                                                                            |
|            | T4CCP0    | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 0.                                                                                                         |

Table 29-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description                                                                                                                                      |
|------------|-----------|----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| V10        | PT1       | I/O      | TTL         | GPIO port T bit 1.                                                                                                                               |
|            | CAN0Tx    | O        | TTL         | CAN module 0 transmit.                                                                                                                           |
|            | EN0RXD1   | I        | TTL         | Ethernet 0 Receive Data 1.                                                                                                                       |
|            | T6CCP1    | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 1.                                                                                                         |
| V11        | PG2       | I/O      | TTL         | GPIO port G bit 2.                                                                                                                               |
|            | EN0TXCK   | I        | TTL         | Ethernet 0 Transmit Clock.                                                                                                                       |
|            | I2C2SCL   | I/O      | OD          | I <sup>2</sup> C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | SSI2XDAT3 | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 3.                                                                                                          |
| V12        | PG6       | I/O      | TTL         | GPIO port G bit 6.                                                                                                                               |

## 29.2 Signals by Signal Name

Table 29-3. Signals by Signal Name

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                           |
|----------|------------|--------------------------|----------|-------------|---------------------------------------|
| AIN0     | G2         | PE3                      | I        | Analog      | Analog-to-digital converter input 0.  |
| AIN1     | G1         | PE2                      | I        | Analog      | Analog-to-digital converter input 1.  |
| AIN2     | H2         | PE1                      | I        | Analog      | Analog-to-digital converter input 2.  |
| AIN3     | H3         | PE0                      | I        | Analog      | Analog-to-digital converter input 3.  |
| AIN4     | B2         | PD7                      | I        | Analog      | Analog-to-digital converter input 4.  |
| AIN5     | B3         | PD6                      | I        | Analog      | Analog-to-digital converter input 5.  |
| AIN6     | B4         | PD5                      | I        | Analog      | Analog-to-digital converter input 6.  |
| AIN7     | A4         | PD4                      | I        | Analog      | Analog-to-digital converter input 7.  |
| AIN8     | B5         | PE5                      | I        | Analog      | Analog-to-digital converter input 8.  |
| AIN9     | A5         | PE4                      | I        | Analog      | Analog-to-digital converter input 9.  |
| AIN10    | C6         | PB4                      | I        | Analog      | Analog-to-digital converter input 10. |
| AIN11    | B6         | PB5                      | I        | Analog      | Analog-to-digital converter input 11. |
| AIN12    | D1         | PD3                      | I        | Analog      | Analog-to-digital converter input 12. |
| AIN13    | D2         | PD2                      | I        | Analog      | Analog-to-digital converter input 13. |
| AIN14    | C1         | PD1                      | I        | Analog      | Analog-to-digital converter input 14. |
| AIN15    | C2         | PD0                      | I        | Analog      | Analog-to-digital converter input 15. |
| AIN16    | J1         | PK0                      | I        | Analog      | Analog-to-digital converter input 16. |
| AIN17    | J2         | PK1                      | I        | Analog      | Analog-to-digital converter input 17. |
| AIN18    | K1         | PK2                      | I        | Analog      | Analog-to-digital converter input 18. |
| AIN19    | K2         | PK3                      | I        | Analog      | Analog-to-digital converter input 19. |
| AIN20    | A7         | PE6                      | I        | Analog      | Analog-to-digital converter input 20. |
| AIN21    | B7         | PE7                      | I        | Analog      | Analog-to-digital converter input 21. |
| AIN22    | A8         | PP7                      | I        | Analog      | Analog-to-digital converter input 22. |
| AIN23    | B8         | PP6                      | I        | Analog      | Analog-to-digital converter input 23. |
| C0+      | L2         | PC6                      | I        | Analog      | Analog comparator 0 positive input.   |
| C0-      | K3         | PC7                      | I        | Analog      | Analog comparator 0 negative input.   |
| C0o      | C2<br>G18  | PD0 (5)<br>PL2 (5)       | O        | TTL         | Analog comparator 0 output.           |
| C1+      | M1         | PC5                      | I        | Analog      | Analog comparator 1 positive input.   |
| C1-      | M2         | PC4                      | I        | Analog      | Analog comparator 1 negative input.   |
| C1o      | C1<br>J18  | PD1 (5)<br>PL3 (5)       | O        | TTL         | Analog comparator 1 output.           |
| C2+      | D6         | PP0                      | I        | Analog      | Analog comparator 2 positive input.   |
| C2-      | D7         | PP1                      | I        | Analog      | Analog comparator 2 negative input.   |
| C2o      | D2         | PD2 (5)                  | O        | TTL         | Analog comparator 2 output.           |
| CAN0Rx   | V3<br>W10  | PA0 (7)<br>PT0 (7)       | I        | TTL         | CAN module 0 receive.                 |
| CAN0Tx   | W3<br>V10  | PA1 (7)<br>PT1 (7)       | O        | TTL         | CAN module 0 transmit.                |

Table 29-3. Signals by Signal Name (continued)

| Pin Name    | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                                                                                                                                   |
|-------------|------------|--------------------------|----------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------|

|----------|----------------------------------------------------------------------------------------------------------------|--------------------------|----------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USB0ID   | A16                                                                                                            | PB0                      | I        | Analog      | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side).                                                     |
| USB0NXT  | B13                                                                                                            | PP2 (14)                 | O        | TTL         | Asserted by the external PHY to throttle all data types.                                                                                                                                                                                                                                                          |
| USB0PFLT | R7<br>B2                                                                                                       | PA7 (5)<br>PD7 (5)       | I        | TTL         | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                                                                         |
| USB0STP  | A17                                                                                                            | PB2 (14)                 | O        | TTL         | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.                                                                                                                                                                                                            |
| USB0VBUS | B16                                                                                                            | PB1                      | I/O      | Analog      | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                                                                                |
| VBAT     | P19                                                                                                            | fixed                    | -        | Power       | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.                                                                                                                                  |
| VDD      | G10<br>H9<br>J8<br>J9<br>J10<br>K7<br>K8<br>K11<br>N16<br>P17<br>K12<br>L10<br>L11<br>L12<br>M11<br>M12<br>P10 | fixed                    | -        | Power       | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                           |
| VDDA     | F3                                                                                                             | fixed                    | -        | Power       | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in , regardless of system implementation. |
| VDDC     | H16<br>E10                                                                                                     | fixed                    | -        | Power       | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 30-15 on page 1913 .                 |

Table 29-3. Signals by Signal Name (*continued*)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------|------------|--------------------------|----------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VREFA+   | F4         | fixed                    | -        | Analog      | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 30-44 on page 1935.                                                                                                                               |
| VREFA-   | G5         | fixed                    | -        | Analog      | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 30-44 on page 1935. |
| WAKE     | U18        | fixed                    | I        | TTL         | An external input that brings the processor out of Hibernate mode when asserted.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| XOSC0    | T18        | fixed                    | I        | Analog      | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.                                                                                                                                                                                                                                                                                                                    |
| XOSC1    | T19        | fixed                    | O        | Analog      | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                                                                                                                                                                                                                                                                            |

## 29.3 Signals by Function, Except for GPIO

Table 29-4. Signals by Function, Except for GPIO

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------|----------|------------|----------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADC      | AIN0     | G2         | I        | Analog      | Analog-to-digital converter input 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|          | AIN1     | G1         | I        | Analog      | Analog-to-digital converter input 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|          | AIN23    | B8         | I        | Analog      | Analog-to-digital converter input 23.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|          | VREFA+   | F4         | -        | Analog      | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 30-44 on page 1935.                                                                                                                               |
|          | VREFA-   | G5         | -        | Analog      | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 30-44 on page 1935. |

Table 29-4. Signals by Function, Except for GPIO (*continued*)

| Function                | Pin Name | Pin Number | Pin Type | Buffer Type | Description                         |
|-------------------------|----------|------------|----------|-------------|-------------------------------------|
| Analog Comparators      | C0+      | L2         | I        | Analog      | Analog comparator 0 positive input. |
|                         | C0-      | K3         | I        | Analog      | Analog comparator 0 negative input. |
|                         | C0o      | C2<br>G18  | O        | TTL         | Analog comparator 0 output.         |

|                        | T7CCP0   |                         | I/O      | TTL         | 16/32-Bit Timer 7 Capture/Compare/PWM 0. |

Table 29-4. Signals by Function, Except for GPIO (*continued*)

| Function  | Pin Name | Pin Number       | Pin Type | Buffer Type | Description                                                                                                                                                                                                                                      |
|-----------|----------|------------------|----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |          | M2<br>H4<br>E18  |          |             |                                                                                                                                                                                                                                                  |
|           | T7CCP1   | M1<br>M4<br>F17  | I/O      | TTL         | 16/32-Bit Timer 7 Capture/Compare/PWM 1.                                                                                                                                                                                                         |
| Hibernate | GNDX     | R18              | -        | Power       | GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
|           | HIB      | M17              | O        | TTL         | An output that indicates the processor is in Hibernate mode.                                                                                                                                                                                     |
|           | RTCCLK   | M1<br>W16<br>C12 | O        | TTL         | Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset.                                                                    |
|           | TMPR0    | N18              | I/O      | TTL         | Tamper signal 0.                                                                                                                                                                                                                                 |
|           | TMPR1    | N19              | I/O      | TTL         | Tamper signal 1.                                                                                                                                                                                                                                 |
|           | TMPR2    | G15              | I/O      | TTL         | Tamper signal 2.                                                                                                                                                                                                                                 |
|           | TMPR3    | M18              | I/O      | TTL         | Tamper signal 3.                                                                                                                                                                                                                                 |
|           | VBAT     | P19              | -        | Power       | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.                                                                 |
|           | WAKE     | U18              | I        | TTL         | An external input that brings the processor out of Hibernate mode when asserted.                                                                                                                                                                 |
|           | XOSC0    | T18              | I        | Analog      | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.                                                                  |
|           | XOSC1    | T19              | O        | Analog      | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                          |

Table 29-4. Signals by Function, Except for GPIO (*continued*)

| Function | Pin Name | Pin Number                    | Pin Type | Buffer Type | Description                                                                                                                                      |
|----------|----------|-------------------------------|----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| I2C      | I2C0SCL  | A17                           | I/O      | OD          | I <sup>2</sup> C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|          | I2C0SDA  | B17                           | I/O      | OD          | I <sup>2</sup> C module 0 data.                                                                                                                  |
|          | I2C1SCL  | N15<br>N5                     | I/O      | OD          | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |

|          | USB0D7   | D8             | I/O      | TTL         | USB data 7.                                                                                                                                                                                                                                                   |
|          | USB0DIR  | C12            | O        | TTL         | Indicates that the external PHY is able to accept data from the USB controller.                                                                                                                                                                               |
|          | USB0DM   | B18            | I/O      | Analog      | Bidirectional differential data pin (D- per USB specification) for USB0.                                                                                                                                                                                      |
|          | USB0DP   | C18            | I/O      | Analog      | Bidirectional differential data pin (D+ per USB specification) for USB0.                                                                                                                                                                                      |
|          | USB0EPEN | V5<br>R7<br>B3 | O        | TTL         | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                              |
|          | USB0ID   | A16            | I        | Analog      | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
|          | USB0NXT  | B13            | O        | TTL         | Asserted by the external PHY to throttle all data types.                                                                                                                                                                                                      |
|          | USB0PFLT | R7<br>B2       | I        | TTL         | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                     |
|          | USB0STP  | A17            | O        | TTL         | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.                                                                                                                                                        |
|          | USB0VBUS | B16            | I/O      | Analog      | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                            |

## 29.4 GPIO Pins and Alternate Functions

Table 29-5. GPIO Pins and Alternate Functions

| IO  | Pin | Analog or Special Function <sup>a</sup> | Digital Function (GPIOCTL PMCx Bit Field Encoding) <sup>b</sup> |         |        |   |   |   |        |   |    |    |    |          |
|-----|-----|-----------------------------------------|-----------------------------------------------------------------|---------|--------|---|---|---|--------|---|----|----|----|----------|
|     |     |                                         | 1                                                               | 2       | 3      | 4 | 5 | 6 | 7      | 8 | 11 | 13 | 14 | 15       |

a. The TMPRn signals are digital signals enabled and configured by the Hibernation module. All other signals listed in this column are analog signals.

b. The digital signals that are shaded gray are the power-on default values for the corresponding GPIO pin. Encodings 9, 10, and 12 are not used on this device.

## 29.5 Possible Pin Assignments for Alternate Functions

Table 29-6. Possible Pin Assignments for Alternate Functions

| # of Possible Assignments | Alternate Function | GPIO Function |
|---------------------------|--------------------|---------------|
| one                       | AIN0               | PE3           |
|                           | AIN1               | PE2           |
|                           | AIN10              | PB4           |

Table 29-6. Possible Pin Assignments for Alternate Functions (*continued*)

| # of Possible Assignments | Alternate Function | GPIO Function       |
|---------------------------|--------------------|---------------------|
| five                      | I2C2SCL            | PG2 PL1 PN5 PP5 PR2 |
|                           | I2C2SDA            | PG3 PL0 PN4 PP6 PR3 |
|                           | U0CTS              | PB4 PE6 PG4 PH1 PM4 |

## 29.6 Connections for Unused Signals

Table 29-7 on page 1899 show how to handle signals for functions that are not used in a particular system implementation for devices that are in a 212-ball BGA package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

Table 29-7. Connections for Unused Signals (212-Ball BGA)

| Function       | Signal Name      | Pin Number                                    | Acceptable Practice | Preferred Practice                             |
|----------------|------------------|-----------------------------------------------|---------------------|------------------------------------------------|
| ADC            | VREFA+           | F4                                            | VDDA                | VDDA                                           |
|                | VREFA-           | G5                                            | GND                 | GND                                            |
| GPIO           | PA1(UART0TX)     | W3                                            | NC                  | GND <sup>a</sup>                               |
|                | PA4 (SSI0XDAT0)  | V4                                            | NC                  | GND <sup>b</sup>                               |
|                | All unused GPIOs | -                                             | NC                  | GND                                            |
| Hibernate      | GNDX             | R18                                           | GND                 | GND                                            |
|                | HTB              | M17                                           | NC                  | NC                                             |
|                | VBAT             | P19                                           | NC                  | VDD                                            |
|                | WAKE             | U18                                           | NC                  | GND                                            |
|                | XOSC0            | T18                                           | NC                  | GND                                            |
|                | XOSC1            | T19                                           | NC                  | NC                                             |
| No Connects    | NC               | See NC pin numbers in Table 29-3 on page 1857 | NC                  | NC                                             |
| System Control | GNDX2            | D18                                           | GND                 | GND                                            |
|                | OSC0             | E19                                           | NC                  | GND                                            |
|                | OSC1             | D19                                           | NC                  | NC                                             |
|                | RST              | P18                                           | VDD                 | Pull up as shown in Figure 5-1 on page 228     |
| USB            | USB0DM / PL7     | B18                                           | NC                  | Pull-down to GND with 1K resistor <sup>c</sup> |
|                | USB0DP / PL6     | C18                                           | NC                  | Pull-down to GND with 1K resistor <sup>c</sup> |

a. PA1 (UART0TX) may be enabled as an output by the ROM boot loader if no code is present in the flash and PA0 (UART0RX) receives a valid boot signature. Ensure that this condition will not occur if PA1 is to be connected directly to GND.

b. PA4 (SSI0XDAT0) may be enabled as an output by the ROM boot loader if no code is present in the flash and the SSI0X (PA2, PA3, PA5) receives a valid boot signature. Ensure that this condition will not occur if PA4 is to be connected directly to GND.

c. The ROM boot loader may configure these pins as USB pins if no code is present in the flash therefore they should not be directly connected to ground.

## 30 Electrical Characteristics

### 30.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device. Device reliability may be adversely affected by exposure to absolute-maximum ratings for extended periods.

**Note:** The device is not guaranteed to operate properly at the maximum ratings.

**Table 30-1. Absolute Maximum Ratings**

| Parameter             | Parameter Name <sup>a</sup>                       | Value |     | Unit       |
|-----------------------|---------------------------------------------------|-------|-----|------------|
|                       |                                                   | Min   | Max |            |
| V <sub>DD</sub>       | V <sub>DD</sub> supply voltage                    | 0     | 4   | V          |
| V <sub>DDA</sub>      | V <sub>DDA</sub> supply voltage                   | 0     | 4   | V          |
| V <sub>BAT</sub>      | V <sub>BAT</sub> battery supply voltage           | 0     | 4   | V          |
| V <sub>BATRMP</sub>   | V <sub>BAT</sub> battery supply voltage ramp time | 0     | 0.7 | V/ $\mu$ s |
| V <sub>IN_GPIO</sub>  | Input voltage <sup>b</sup>                        | -0.3  | 4   | V          |
| I <sub>GPIO MAX</sub> | Maximum current per output pin                    | -     | 64  | mA         |
| T <sub>S</sub>        | Unpowered storage temperature range               | -65   | 150 | °C         |
| T <sub>JMAX</sub>     | Maximum junction temperature                      | -     | 125 | °C         |

a. Voltages are measured with respect to GND.

b. Applies to static and dynamic signals including overshoot.

**Important:** This device contains circuitry to protect the I/Os against damage due to high-static voltages; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (see “Connections for Unused Signals” on page 1899).

**Table 30-2. ESD Absolute Maximum Ratings**

| Parameter                                       | Parameter Name                   | Min | Nom | Max | Unit |
|-------------------------------------------------|----------------------------------|-----|-----|-----|------|
| Component-Level ESD Stress Voltage <sup>a</sup> | V <sub>ESDHBM</sub> <sup>b</sup> | -   | -   | 2.0 | kV   |
|                                                 | V <sub>ESDCDM</sub> <sup>c</sup> | -   | -   | 500 | V    |

a. Electrostatic discharge (ESD) is used to measure device sensitivity/immunity to damage caused by electrostatic discharges in device.

b. All pins are HBM compliant to 2 kV for all combinations as per JESD22-A114F, except for the following stress combinations:

- The GPIO pins PM4, PM5, PM6, and PM7 to other pins.

These exceptions are compliant to 500 V and do not require any special handling beyond typical ESD control procedures during assembly operations per JEDEC publication JEP155. Note that these pins do meet the 500 V CDM specification.

c. Level listed is the passing level per EIA-JEDEC JESD22-C101E. JEDEC document JEP157 states that 250 V CDM allows safe manufacturing with a standard ESD control process.

## 30.2 Operating Characteristics

**Table 30-3. Temperature Characteristics**

| Characteristic                       | Symbol | Value                                                                              | Unit |
|--------------------------------------|--------|------------------------------------------------------------------------------------|------|
| Ambient operating temperature range  | $T_A$  | -40 to 85 (industrial temperature part)<br>-40 to 105 (extended temperature part)  | °C   |
| Junction operating temperature range | $T_J$  | -40 to 105 (industrial temperature part)<br>-40 to 125 (extended temperature part) | °C   |

**Table 30-4. 212 BGA Power Dissipation<sup>ab</sup>**

| Parameter | Parameter Name                                  | $T_A$                               | $T_J$                                | Min | Max  | Unit |
|-----------|-------------------------------------------------|-------------------------------------|--------------------------------------|-----|------|------|
| $P_{DI}$  | Industrial temperature device power dissipation | 85 °C (industrial temperature part) | 125 °C (industrial temperature part) | -   | 1018 | mW   |
| $P_{DE}$  | Extended temperature device power dissipation   | 105 °C (extended temperature part)  | 125 °C (extended temperature part)   | -   | 509  | mW   |

- a. If the device exceeds the power dissipation value shown, then modifications such as heat sinks or fans must be used to conform to the limits shown.
- b. A larger power dissipation allowance can be achieved by lowering  $T_A$  as long as  $T_{JMAX}$  shown in Table 30-1 on page 1900 is not exceeded.

**Table 30-5. Thermal Characteristics<sup>a</sup>**

| Characteristic                                        | Symbol        | Value                                                                                                                                    | Unit |
|-------------------------------------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------|------|
| Thermal resistance (junction to ambient) <sup>b</sup> | $\Theta_{JA}$ | 39.3                                                                                                                                     | °C/W |
| Thermal resistance (junction to board) <sup>b</sup>   | $\Theta_{JB}$ | 18.6                                                                                                                                     | °C/W |
| Thermal resistance (junction to case) <sup>b</sup>    | $\Theta_{JC}$ | 12.9                                                                                                                                     | °C/W |
| Thermal metric (junction to top of package)           | $\Psi_{JT}$   | 0.2                                                                                                                                      | °C/W |
| Thermal metric (junction to board)                    | $\Psi_{JB}$   | 18.4                                                                                                                                     | °C/W |
| Junction temperature formula                          | $T_J$         | $T_C + (P \cdot \Psi_{JT})^c$<br>$T_{PCB} + (P \cdot \Psi_{JB})^d$<br>$T_A + (P \cdot \Theta_{JA})^e$<br>$T_B + (P \cdot \Theta_{JB})^f$ | °C   |

- a. For more details about thermal metrics and definitions, see the *Semiconductor and IC Package Thermal Metrics Application Report* (literature number [SPRA953](#)).
- b. Junction to ambient thermal resistance ( $\Theta_{JA}$ ), junction to board thermal resistance ( $\Theta_{JB}$ ), and junction to case thermal resistance ( $\Theta_{JC}$ ) numbers are determined by a package simulator.
- c.  $T_C$  is the case temperature and P is the device power consumption.
- d.  $T_{PCB}$  is the temperature of the board acquired by following the steps listed in the EAI/JESD 51-8 standard summarized in the *Semiconductor and IC Package Thermal Metrics Application Report* (literature number [SPRA953](#)). P is the device power consumption.
- e. Because  $\Theta_{JA}$  is highly variable and based on factors such as board design, chip/pad size, altitude, and external ambient temperature, it is recommended that equations containing  $\Psi_{JT}$  and  $\Psi_{JB}$  be used for best results.
- f.  $T_B$  is temperature of the board.

g.  $\Theta_{JB}$  is not a pure reflection of the internal resistance of the package because it includes the resistance of the testing board and environment. It is recommended that equations containing  $\Psi_{JT}$  and  $\Psi_{JB}$  be used for best results.

### 30.3 Recommended Operating Conditions

The following sections describe the recommended DC operating conditions and GPIO operating characteristics for the device.

#### 30.3.1 DC Operating Conditions

**Table 30-6. Recommended DC Operating Conditions**

| Parameter   | Parameter Name                            | Min  | Nom | Max  | Unit |
|-------------|-------------------------------------------|------|-----|------|------|
| $V_{DD}$    | $V_{DD}$ supply voltage                   | 2.97 | 3.3 | 3.63 | V    |
| $V_{DDA}^a$ | $V_{DDA}$ supply voltage                  | 2.97 | 3.3 | 3.63 | V    |
| $V_{DDC}$   | $V_{DDC}$ supply voltage, Run mode        | 1.14 | 1.2 | 1.32 | V    |
| $V_{DDCDS}$ | $V_{DDC}$ supply voltage, Deep-sleep mode | 0.85 | -   | 0.95 | V    |

a. To ensure proper operation,  $V_{DDA}$  must be powered up before  $V_{DD}$  if sourced from different supplies, or connected to the same supply as  $V_{DD}$ . There is not a restriction on order for powering off.

#### 30.3.2 Recommended GPIO Operating Characteristics

Two types of pads are provided on the device:

- Fast GPIO pads: These pads provide variable, programmable drive strength and optimized voltage output levels.
- Slow GPIO pads: These pads provide 2-mA drive strength and are designed to be sensitive to voltage inputs. The following GPIOs port pins are designed with Slow GPIO Pads:
  - PJ1

All other GPIOs have a fast GPIO pad-type.

**Note:** Port pins PL6 and PL7 operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIO2R**, **GPIO4R**, **GPIO8R**, **GPIO12R**, **GPIO16R**, and **GPIO20R**.

**Note:** Port pins PM[7:4] operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIO12R** register, apply to these port pins.

Table 30-7 on page 1902 detail the GPIO operating conditions for these two different pad types.

**Table 30-7. Recommended FAST GPIO Pad Operating Conditions**

| Parameter | Parameter Name                                  | Min             | Nom | Max             | Unit |
|-----------|-------------------------------------------------|-----------------|-----|-----------------|------|
| $V_{IH}$  | Fast GPIO high-level input voltage              | $0.65 * V_{DD}$ | -   | 4               | V    |
| $I_{IH}$  | Fast GPIO high-level input current <sup>a</sup> | -               | -   | 300             | nA   |
| $V_{IL}$  | Fast GPIO low-level input voltage               | 0               | -   | $0.35 * V_{DD}$ | V    |
| $I_{IL}$  | Fast GPIO low-level input current <sup>a</sup>  | -               | -   | -200            | nA   |
| $V_{HYS}$ | Fast GPIO Input Hysteresis                      | 0.49            | -   | -               | V    |
| $V_{OH}$  | Fast GPIO High-level output voltage             | 2.4             | -   | -               | V    |
| $V_{OL}$  | Fast GPIO Low-level output voltage              | -               | -   | 0.40            | V    |

**Table 30-7. Recommended FAST GPIO Pad Operating Conditions (continued)**

| Parameter | Parameter Name                                               | Min  | Nom | Max | Unit |
|-----------|--------------------------------------------------------------|------|-----|-----|------|
| $I_{OH}$  | Fast GPIO High-level source current, $V_{OH}=2.4\text{ V}^b$ |      |     |     |      |
|           | 2-mA Drive                                                   | 2.0  | -   | -   | mA   |
|           | 4-mA Drive                                                   | 4.0  | -   | -   | mA   |
|           | 8-mA Drive                                                   | 8.0  | -   | -   | mA   |
|           | 10-mA Drive                                                  | 10.0 | -   | -   | mA   |
|           | 12-mA Drive                                                  | 12.0 | -   | -   | mA   |
| $I_{OL}$  | Fast GPIO Low-level sink current, $V_{OL}=0.4\text{ V}^b$    |      |     |     |      |
|           | 2-mA Drive                                                   | 2.0  | -   | -   | mA   |
|           | 4-mA Drive                                                   | 4.0  | -   | -   | mA   |
|           | 8-mA Drive                                                   | 8.0  | -   | -   | mA   |
|           | 10-mA Drive                                                  | 10.0 | -   | -   | mA   |
|           | 12-mA Drive                                                  | 12.0 | -   | -   | mA   |
|           | 12-mA Drive overdriven to 18-mA                              | 18.0 | -   | -   | mA   |

a. Output/pull-up/pull-down disabled; only input enabled

b.  $I_O$  specifications reflect the maximum current where the corresponding output voltage meets the  $V_{OH}/V_{OL}$  thresholds.  $I_O$  current can exceed these limits (subject to absolute maximum ratings).

**Table 30-8. Recommended Slow GPIO Pad Operating Conditions**

| Parameter | Parameter Name                                     | Min             | Nom | Max             | Unit |
|-----------|----------------------------------------------------|-----------------|-----|-----------------|------|
| $V_{IH}$  | Slow GPIO high-level input voltage                 | $0.65 * V_{DD}$ | -   | 4               | V    |
| $I_{IH}$  | Slow GPIO high-level input current <sup>a</sup>    | -               | -   | 4.1             | nA   |
| $V_{IL}$  | Slow GPIO low-level input voltage                  | 0               | -   | $0.35 * V_{DD}$ | V    |
| $I_{IL}$  | Slow GPIO low-level input current <sup>a</sup>     | -               | -   | -1              | nA   |
| $V_{HYS}$ | Slow GPIO Input Hysteresis                         | 0.49            | -   | -               | V    |
| $V_{OH}$  | Slow GPIO High-level output voltage                | 2.4             | -   | -               | V    |
| $V_{OL}$  | Slow GPIO Low-level output voltage                 | -               | -   | 0.4             | V    |
| $I_{OH}$  | High-level source current, $V_{OH}=2.4\text{ V}^b$ |                 |     |                 |      |
|           | 2-mA Drive                                         | 2.0             | -   | -               | mA   |
| $I_{OL}$  | Low-level sink current, $V_{OL}=0.4\text{ V}^b$    |                 |     |                 |      |
|           | 2-mA Drive                                         | 2.0             | -   | -               | mA   |

a. Output/pull-up/pull-down disabled; only input enabled.

b.  $I_O$  specifications reflect the maximum current where the corresponding output voltage meets the  $V_{OH}/V_{OL}$  thresholds.  $I_O$  current can exceed these limits (subject to absolute maximum ratings).

### 30.3.2.1 GPIO Current Restrictions

**Table 30-9. GPIO Current Restrictions<sup>a</sup>**

| Parameter  | Parameter Name                                                | Min | Nom | Max | Unit |
|------------|---------------------------------------------------------------|-----|-----|-----|------|
| $I_{MAXL}$ | Cumulative maximum GPIO current per side, left <sup>b</sup>   | -   | -   | 110 | mA   |
| $I_{MAXB}$ | Cumulative maximum GPIO current per side, bottom <sup>b</sup> | -   | -   | 116 | mA   |
| $I_{MAXR}$ | Cumulative maximum GPIO current per side, right <sup>b</sup>  | -   | -   | 110 | mA   |

**Table 30-9. GPIO Current Restrictions (continued)**

| Parameter  | Parameter Name                                             | Min | Nom | Max | Unit |
|------------|------------------------------------------------------------|-----|-----|-----|------|
| $I_{MAXT}$ | Cumulative maximum GPIO current per side, top <sup>b</sup> | -   | -   | 88  | mA   |

a. Based on design simulations, not tested in production.

b. Sum of sink and source current for GPIOs as shown in Table 30-10 on page 1904.

**Table 30-10. Maximum GPIO Package Side Assignments**

| Side   | GPIOs                                                                             |
|--------|-----------------------------------------------------------------------------------|
| Left   | PB[6-7], PC[4-7], PD[0-3], PE[0-3], PH[0-7], PJ[6-7], PK[0-3], PQ[0-3,7], PR[0-5] |
| Bottom | PA[0-7], PF[0-7], PG[0-7], PK[4-7], PN[6-7], PR[3,6-7], PQ[5-6], PS[4-7], PT[0-1] |
| Right  | PB[0-3], PJ[2-5], PL[0-5,6-7], PM[0-7], PT[2-3]                                   |
| Top    | PB[4-5], PC[0-3], PD[4-7], PE[4-7], PJ[0-1], PN[0-5], PP[0-7], PQ[4], PS[0-3],    |

**I/O Reliability**

For typical continuous drive applications, I/O pins configured between 2 mA and 12 mA and operating at -40 to 85°C, meet the standard 10-year lifetime reliability. If a continuous current sink of 18 mA is required, then operation is limited to 0 to 75°C in order to meet the standard 10-year reliability.

At 105°C, I/O configured for continuous drive meet the standard 2.5 year lifetime reliability.

In typical switching applications (40% switch rate) operating at -40 to 85°C, all I/O configurations except 2 mA meet the standard 10-year lifetime reliability with 50-pF loading. By limiting the capacitive loading to 20 pF for an I/O configured to 2 mA, the 10-year lifetime reliability can be met at -40 to 85°C.

In typical switching applications (40% switch rate) operating at 105°C, all I/O configurations except 2 mA meet the standard 2.5-year lifetime reliability. By reducing the capacitive loading to 20 pF with a typical switching rate at 105°C, a 2-mA I/O configuration meets a 2.5 year lifetime reliability.

**30.4 Load Conditions**

Table 30-11 on page 1905 contains the load conditions used for timing measurements.

**Figure 30-1. Load Conditions**

Table 30-11. Load Conditions

| Signals                               | Load Value (C <sub>L</sub> ) |
|---------------------------------------|------------------------------|
| EPIOS[35:0] SDRAM interface           | 30 pF                        |
| EPIOS[35:0] General-Purpose interface |                              |
| EPIOS[35:0] Host-Bus interface        |                              |
| EPIOS[35:0] PSRAM interface           | 40 pF                        |
| All other digital I/O signals         | 50 pF                        |

## 30.5 JTAG and Boundary Scan

Table 30-12. JTAG Characteristics

| Parameter No. | Parameter             | Parameter Name                                                            | Min | Nom                 | Max | Unit |
|---------------|-----------------------|---------------------------------------------------------------------------|-----|---------------------|-----|------|
| J1            | F <sub>TCK</sub>      | TCK operational clock frequency <sup>a</sup>                              | 0   | -                   | 10  | MHz  |
| J2            | T <sub>TCK</sub>      | TCK operational clock period                                              | 100 | -                   | -   | ns   |
| J3            | T <sub>TCK_LOW</sub>  | TCK clock Low time                                                        | -   | t <sub>TCK</sub> /2 | -   | ns   |
| J4            | T <sub>TCK_HIGH</sub> | TCK clock High time                                                       | -   | t <sub>TCK</sub> /2 | -   | ns   |
| J5            | T <sub>TCK_R</sub>    | TCK rise time                                                             | 0   | -                   | 10  | ns   |
| J6            | T <sub>TCK_F</sub>    | TCK fall time                                                             | 0   | -                   | 10  | ns   |
| J7            | T <sub>TMS_SU</sub>   | TMS setup time to TCK rise                                                | 8   | -                   | -   | ns   |
| J8            | T <sub>TMS_HLD</sub>  | TMS hold time from TCK rise                                               | 4   | -                   | -   | ns   |
| J9            | T <sub>TDI_SU</sub>   | TDI setup time to TCK rise                                                | 18  | -                   | -   | ns   |
| J10           | T <sub>TDI_HLD</sub>  | TDI hold time from TCK rise                                               | 4   | -                   | -   | ns   |
| J11           | T <sub>TDO_ZDV</sub>  | TCK fall to Data Valid from High-Z, 2-mA drive                            | -   | 13                  | 35  | ns   |
|               |                       | TCK fall to Data Valid from High-Z, 4-mA drive                            |     | 9                   | 26  | ns   |
|               |                       | TCK fall to Data Valid from High-Z, 8-mA drive                            |     | 8                   | 26  | ns   |
|               |                       | TCK fall to Data Valid from High-Z, 8-mA drive with slew rate control     |     | 10                  | 29  | ns   |
|               |                       | TCK fall to Data Valid from High-Z, 10-mA drive                           |     | 11                  | 13  | ns   |
|               |                       | TCK fall to Data Valid from High-Z, 12-mA drive                           |     | 11                  | 14  | ns   |
| J12           | T <sub>TDO_DV</sub>   | TCK fall to Data Valid from Data Valid, 2-mA drive                        | -   | 14                  | 20  | ns   |
|               |                       | TCK fall to Data Valid from Data Valid, 4-mA drive                        |     | 10                  | 26  | ns   |
|               |                       | TCK fall to Data Valid from Data Valid, 8-mA drive                        |     | 8                   | 21  | ns   |
|               |                       | TCK fall to Data Valid from Data Valid, 8-mA drive with slew rate control |     | 10                  | 26  | ns   |
|               |                       | TCK fall to Data Valid from Data Valid, 10-mA drive                       |     | 12                  | 14  | ns   |
|               |                       | TCK fall to Data Valid from Data Valid, 12-mA drive                       |     | 12                  | 15  | ns   |
| J13           | T <sub>TDO_DVZ</sub>  | TCK fall to High-Z from Data Valid, 2-mA drive                            | -   | 7                   | 16  | ns   |
|               |                       | TCK fall to High-Z from Data Valid, 4-mA drive                            |     | 7                   | 16  | ns   |
|               |                       | TCK fall to High-Z from Data Valid, 8-mA drive                            |     | 7                   | 16  | ns   |
|               |                       | TCK fall to High-Z from Data Valid, 8-mA drive with slew rate control     |     | 8                   | 19  | ns   |
|               |                       | TCK fall to High-Z from Data Valid, 10-mA drive                           |     | 20                  | 22  | ns   |
|               |                       | TCK fall to High-Z from Data Valid, 12-mA drive                           |     | 20                  | 25  | ns   |

a. A ratio of at least 8:1 must be kept between the system clock and TCK.

## 30.6 Power and Brown-Out

Table 30-13. Power and Brown-Out Levels<sup>a</sup>

| Parameter No. | Parameter          | Parameter Name                                | Min  | Nom  | Max      | Unit    |
|---------------|--------------------|-----------------------------------------------|------|------|----------|---------|
| P1            | $T_{VDDA\_RISE}$   | Analog Supply voltage ( $V_{DDA}$ ) rise time | -    | -    | $\infty$ | $\mu s$ |
| P2            | $T_{VDD\_RISE}$    | I/O Supply voltage ( $V_{DD}$ ) rise time     | -    | -    | $\infty$ | $\mu s$ |
| P3            | $T_{VDDC\_RISE}^b$ | Core Supply Voltage ( $V_{DDC}$ ) rise time   | 10   | -    | 150      | $\mu s$ |
| P4            | $V_{POR}$          | Power-On Reset Threshold                      | 2.00 | 2.30 | 2.55     | V       |
| P5            | $V_{DDA\_POK}$     | $V_{DDA}$ Power-OK Threshold (Rising Edge)    | 2.67 | 2.82 | 2.97     | V       |
| P6            | $V_{DDA\_BOR0}$    | $V_{DDA}$ Brown-Out Reset Threshold           | 2.71 | 2.80 | 2.89     | V       |
| P7            | $V_{DD\_POK}$      | $V_{DD}$ Power-OK Threshold (Rising Edge)     | 2.65 | 2.80 | 2.90     | V       |
|               |                    | $V_{DD}$ Power-OK Threshold (Falling Edge)    | 2.67 | 2.76 | 2.85     | V       |
| P8            | $V_{DD\_BOR0}$     | $V_{DD}$ Brown-Out Reset Threshold            | 2.77 | 2.86 | 2.95     | V       |
| P9            | $V_{DDC\_POK}$     | $V_{DDC}$ Power-OK Threshold (Rising Edge)    | 0.85 | 0.95 | 1.10     | V       |
|               |                    | $V_{DDC}$ Power-OK Threshold (Falling Edge)   | 0.71 | 0.80 | 0.85     | V       |

a. All values in this table are based on simulation and are pending characterization.

b. The MIN and MAX values are based on an external filter capacitor load within the range of  $C_{LDO}$ . Please refer to "On-Chip Low Drop-Out (LDO) Regulator" on page 1913 for the  $C_{LDO}$  value.

### 30.6.1 V<sub>DDA</sub> Levels

The V<sub>DDA</sub> supply has three monitors:

- Power-On Reset (POR)
- Power-OK (POK)
- Brown Out Reset (BOR)

The POR monitor is used to keep the analog circuitry in reset until the V<sub>DDA</sub> supply has reached the correct range for the analog circuitry to begin operating. The POK monitor is used to keep the digital circuitry in reset until the V<sub>DDA</sub> power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. The BOR monitor is used to generate a reset to the device or assert an interrupt if the V<sub>DDA</sub> supply drops below its operational range.

**Note:** V<sub>DDA</sub> BOR and V<sub>DD</sub> BOR events are a combined BOR to the system logic, such that if either BOR event occurs, the following bits are affected:

- BORRIS bit in the **Raw Interrupt Status (RIS)** register, System Control offset 0x050. See page 265.
- BORMIS bit in the **Masked Interrupt Status and Clear (MISC)** register, System Control offset 0x058. This bit is set only if the BORIM bit in the **Interrupt Mask Control (IMC)** register has been set. See page 267 and page 269.
- BOR bit in the **Reset Cause (RESC)** register, System Control offset 0x05C. This bit is set only if either of the BOR events have been configured to initiate a reset. See page 271.

In addition, the following bits control both BOR events:

- BORIM bit in the **Interrupt Mask Control (IMC)** register, System Control offset 0x054.
- VDDA\_UBOR0 and VDD\_UBOR0 bits in the **Power-Temperature Cause (PWRTC)** register.

Please refer to “System Control” on page 224 for more information on how to configure these registers.

Figure 30-4 on page 1908 shows the relationship between V<sub>DDA</sub>, POK, POR and a BOR event.

Figure 30-4. Power and Brown-Out Assertions vs  $V_{DDA}$  Levels

### 30.6.2 $V_{DD}$ Levels

The  $V_{DD}$  supply has two monitors:

- Power-OK (POK)
- Brown Out Reset (BOR)

The POK monitor is used to keep the digital circuitry in reset until the  $V_{DD}$  power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. The BOR monitor is used to generate a reset to the device or assert an interrupt if the  $V_{DD}$  supply drops below its operational range.

**Note:**  $V_{DDA}$  BOR and  $V_{DD}$  BOR events are a combined BOR to the system logic, such that if either BOR event occurs, the following bits are affected:

- BORRIS bit in the **Raw Interrupt Status (RIS)** register, System Control offset 0x050. See page 265.
- BORMIS bit in the **Masked Interrupt Status and Clear (MISC)** register, System Control offset 0x058. This bit is set only if the BORIM bit in the **Interrupt Mask Control (IMC)** register has been set. See page 267 and page 269.
- BOR bit in the **Reset Cause (RESC)** register, System Control offset 0x05C. This bit is set only if either of the BOR events have been configured to initiate a reset. See page 271.

In addition, the following bits control both BOR events:

- BORIM bit in the **Interrupt Mask Control (IMC)** register, System Control offset 0x054.
- VDDA\_UBOR0 and VDD\_UBOR0 bits in the **Power-Temperature Cause (PWRTC)** register.

Please refer to “System Control” on page 224 for more information on how to configure these registers.

Figure 30-5 on page 1909 shows the relationship between  $V_{DD}$ , POK, POR and a BOR event.

**Figure 30-5. Power and Brown-Out Assertions vs  $V_{DD}$  Levels**

### 30.6.3 $V_{DDC}$ Levels

The  $V_{DDC}$  supply has one monitor, the Power-OK (POK). The POK monitor is used to keep the digital circuitry in reset until the  $V_{DDC}$  power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. Figure 30-6 on page 1910 shows the relationship between POK and  $V_{DDC}$ .

Figure 30-6. POK Assertion vs  $V_{DDC}$ 

### 30.6.4 Response

#### 30.6.4.1 $V_{DD}$ Glitch Response

Figure 30-7 on page 1910 shows the response of the BOR and the POR circuit to glitches on the VDD supply.

Figure 30-7. POR-BOR  $V_{DD}$  Glitch Response

#### 30.6.4.2 $V_{DD}$ Droop Response

Figure 30-8 on page 1911 shows the response of the BOR and the POR monitors to a drop on the VDD supply.

Figure 30-8. POR-BOR  $V_{DD}$  Droop Response

## 30.7 Reset

Table 30-14. Reset Characteristics<sup>a</sup>

| Parameter No. | Parameter       | Parameter Name                                               | Min  | Nom            | Max | Unit |
|---------------|-----------------|--------------------------------------------------------------|------|----------------|-----|------|
| R1            | $T_{DPODLY}^b$  | Digital POR to Internal Reset assertion delay <sup>c</sup>   | 0.44 | -              | 126 | μs   |
| R2            | $T_{IRTOUT}^b$  | Internal Reset timeout                                       | -    | 7              | -   | ms   |
| R3            | $T_{BOR0DLY}^b$ | BOR0 to Internal Reset assertion delay <sup>c</sup>          | 0.44 | -              | 125 | μs   |
| R4            | $T_{RSTMIN}$    | Minimum RST pulse width                                      | -    | $0.25^d/100^e$ | -   | μs   |
| R5            | $T_{IRHWDLY}$   | RST to Internal Reset assertion delay                        | -    | 0.85           | -   | μs   |
| R6            | $T_{IRSWR}^b$   | Internal reset timeout after software-initiated system reset | -    | 2.44           | -   | μs   |
| R7            | $T_{IRWDR}^b$   | Internal reset timeout after Watchdog reset                  | -    | 2.44           | -   | μs   |
| R8            | $T_{IRMFR}^b$   | Internal reset timeout after MOSC failure reset              | -    | 2.44           | -   | μs   |

a. Minimum timings are for reset assertion using PIOSC as a clock source. Maximum timings are for reset assertion using LFIOSC in Deep-Sleep Operation.

b. These values are based on simulation.

c. Timing values are dependent on the  $V_{DD}$  power-down ramp rate.

d. Standard operation.

e. Deep-sleep operation with PIOSC powered down.

**Figure 30-9. Digital Power-On Reset Timing**

The digital Power-On Reset is only released when the analog Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges.

**Figure 30-10. Brown-Out Reset Timing****Figure 30-11. External Reset Timing ( $\overline{\text{RST}}$ )**

## 30.8 On-Chip Low Drop-Out (LDO) Regulator

Table 30-15. LDO Regulator Characteristics

| Parameter        | Parameter Name                                                        | Min  | Nom | Max  | Unit |
|------------------|-----------------------------------------------------------------------|------|-----|------|------|
| C <sub>LDO</sub> | External filter capacitor size for internal power supply <sup>a</sup> | 2.5  | -   | 4.0  | μF   |
| ESR              | Filter capacitor equivalent series resistance                         | 0    | -   | 100  | mΩ   |
| ESL              | Filter capacitor equivalent series inductance                         | -    | -   | 0.5  | nH   |
| V <sub>LDO</sub> | LDO output voltage, Run mode                                          | 1.13 | 1.2 | 1.27 | V    |

**Table 30-15. LDO Regulator Characteristics (continued)**

| Parameter           | Parameter Name | Min | Nom | Max | Unit |
|---------------------|----------------|-----|-----|-----|------|
| I <sub>INRUSH</sub> | Inrush current | 50  | -   | 250 | mA   |

a. The capacitor should be connected as close as possible to pin E10.

## 30.9 Clocks

The following sections provide specifications on the various clock sources and mode.

### 30.9.1 PLL Specifications

The following tables provide specifications for using the PLL.

**Table 30-16. Phase Locked Loop (PLL) Characteristics**

| Parameter             | Parameter Name                                                                         | Min | Nom | Max                            | Unit |
|-----------------------|----------------------------------------------------------------------------------------|-----|-----|--------------------------------|------|
| F <sub>REF_XTAL</sub> | Crystal reference                                                                      | 5   | -   | 25                             | MHz  |
| F <sub>REF_EXT</sub>  | External clock reference                                                               | 5   | -   | 25                             | MHz  |
| F <sub>PLL</sub>      | PLL VCO frequency at 1.2V <sup>a</sup>                                                 | -   | -   | 480                            | MHz  |
| F <sub>PLLS</sub>     | PLL VCO frequency at 0.9V <sup>b</sup>                                                 | -   | -   | 480                            | MHz  |
| T <sub>READY</sub>    | PLL lock time (enabling the PLL) when PLL is transitioning from power down to power up | -   | -   | 512 * (reference clock period) | μs   |
|                       | PLL lock time when the PLL VCO frequency is changed (PLL is already enabled)           | -   | -   | 128 * (reference clock period) | μs   |
|                       | PLL lock time, changing the OSCSRC between MOSC and PIOSC                              | -   | -   | 128 * (reference clock period) | μs   |

a. PLL frequency is manually calculated using the values in the PLLFREQ0 and PLLFREQ1 registers.

b. If the LDO is dropped to 0.9V, the system must be run 1/4 of the maximum frequency at most. The Q value in the **PLLFREQ1** register must be set to 0x3 rather than using the PSYSDIV field in the **RSCLKCFG** register for the divisor.

#### 30.9.1.1 PLL Configuration

The PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the PLL to drive the output. The PLL is controlled using the **PLLFREQ0**, **PLLFREQ1** and **PLLSTAT** registers. Changes made to these registers do not become active until after the NEWFREQ bit in the **RSCLKCFG** register is enabled.

The clock source for the main PLL is selected by configuring the PLLSRC field in the **Run and Sleep Clock Configuration (RSCLKCFG)** register.

The PLL allows for the generation of system clock frequencies in excess of the reference clock provided. The reference clocks for the PLL are the PIOSC and the MOSC. The PLL is controlled by two registers, **PLLFREQ0** and **PLLFREQ1**. The PLL VCO frequency (f<sub>VCO</sub>) is determined through the following calculation:

$$f_{VCO} = f_{IN} * MDIV$$

where

$$f_{IN} = f_{XTAL} / (Q+1)(N+1) \text{ or } f_{PIOSC} / (Q+1)(N+1)$$

$$MDIV = MINT + (MFRAC / 1024)$$

The Q and N values are programmed in the **PLLREQ1** register. Note that to reduce jitter, MFRAC should be programmed to 0x0.

When the PLL is active, the system clock frequency (SysClk) is calculated using the following equation:

$$\text{SysClk} = f_{\text{VCO}} / (\text{PSYSDIV} + 1)$$

The PLL system divisor factor (PSYSDIV) determines the value of the system clock. Table 5-6 on page 242 shows how the system divisor encodings affect the system clock frequency when the  $f_{\text{VCO}} = 480 \text{ MHz}$ .

**Table 30-17. System Divisor Factors for  $f_{\text{VCO}}=480 \text{ MHz}$**

| System Clock (SYSCLK) (MHz) | $f_{\text{VCO}} \text{ (MHz)} = 480 \text{ MHz}$ |
|-----------------------------|--------------------------------------------------|
|                             | System Divisors (PSYSDIV + 1) <sup>a</sup>       |
| 120                         | 4                                                |
| 60                          | 8                                                |
| 48                          | 10                                               |
| 30                          | 16                                               |
| 24                          | 20                                               |
| 12                          | 40                                               |
| 6                           | 80                                               |

a. The use of non-integer divisors introduce additional jitter which may affect interface performance.

If the main oscillator provides the clock reference to the PLL, the translation provided by hardware and used to program the PLL is available for software in the **PLL Frequency n (PLLREQn)** registers (see page 296). The internal translation provides a translation within  $\pm 1\%$  of the targeted PLL VCO frequency. Table 5-7 on page 242 shows the actual PLL frequency and error for a given crystal choice.

Table 5-7 on page 242 provides examples of the programming expected for the **PLLREQ0** and **PLLREQ1** registers. The first column specifies the input crystal frequency and the last column displays the PLL frequency given the values of MINT and N, when Q=0.

**Table 30-18. Actual PLL Frequency<sup>a</sup>**

| Crystal Frequency (MHz) | MINT (Decimal Value) | MINT (Hexadecimal Value) | N   | Reference Frequency (MHz) <sup>b</sup> | PLL Frequency (MHz) |
|-------------------------|----------------------|--------------------------|-----|----------------------------------------|---------------------|
| 5                       | 64                   | 0x40                     | 0x0 | 5                                      | 320                 |
| 6                       | 160                  | 0x35                     | 0x2 | 2                                      | 320                 |
| 8                       | 40                   | 0x28                     | 0x0 | 8                                      | 320                 |
| 10                      | 32                   | 0x20                     | 0x0 | 10                                     | 320                 |
| 12                      | 80                   | 0x50                     | 0x2 | 4                                      | 320                 |
| 16                      | 20                   | 0x14                     | 0x0 | 16                                     | 320                 |
| 18                      | 160                  | 0xA0                     | 0x8 | 2                                      | 320                 |
| 20                      | 16                   | 0x10                     | 0x0 | 20                                     | 320                 |
| 24                      | 40                   | 0x28                     | 0x2 | 8                                      | 320                 |
| 25                      | 64                   | 0x40                     | 0x4 | 5                                      | 320                 |
| 5                       | 96                   | 0x60                     | 0x0 | 5                                      | 480                 |

Table 30-18. Actual PLL Frequency (*continued*)

| Crystal Frequency (MHz) | MINT (Decimal Value) | MINT (Hexadecimal Value) | N   | Reference Frequency (MHz) <sup>b</sup> | PLL Frequency (MHz) |
|-------------------------|----------------------|--------------------------|-----|----------------------------------------|---------------------|
| 6                       | 80                   | 0x50                     | 0x0 | 6                                      | 480                 |
| 8                       | 60                   | 0x3C                     | 0x0 | 8                                      | 480                 |
| 10                      | 48                   | 0x30                     | 0x0 | 10                                     | 480                 |
| 12                      | 40                   | 0x28                     | 0x0 | 12                                     | 480                 |
| 16                      | 30                   | 0x1E                     | 0x0 | 16                                     | 480                 |
| 18                      | 80                   | 0x50                     | 0x2 | 6                                      | 480                 |
| 20                      | 24                   | 0x18                     | 0x0 | 20                                     | 480                 |
| 24                      | 20                   | 0x14                     | 0x0 | 24                                     | 480                 |
| 25                      | 96                   | 0x60                     | 0x4 | 5                                      | 480                 |

a. For all examples listed, Q=0

b. For a given crystal frequency, N should be chosen such that the reference frequency is within 4 to 30 MHz.

### 30.9.2 PIOSC Specifications

Table 30-19. PIOSC Clock Characteristics

| Parameter          | Parameter Name                                                                                                                                                  | Min | Nom | Max              | Unit |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|-----|------------------|------|
| F <sub>PIOSC</sub> | Internal 16-MHz precision oscillator frequency variance (factory calibrated at 25 °C and 3.3 V) across the specified voltage and temperature range <sup>a</sup> | -   | -   | ±3% <sup>b</sup> | -    |
| T <sub>START</sub> | PIOSC startup time <sup>c</sup>                                                                                                                                 | -   | -   | 1                | μs   |

a. This parameter value remains valid if recalibration occurs.

b. ±3% can only be met with VDD±5%.

c. PIOSC startup time is part of reset and is included in the internal reset timeout value (T<sub>IRTOU</sub>) given in Table 30-14 on page 1911. Note that the T<sub>START</sub> value is based on simulation.

### 30.9.3 Low-Frequency Internal Oscillator Specifications

Table 30-20. Low-Frequency Oscillator Characteristics

| Parameter           | Parameter Name                              | Min             | Nom | Max             | Unit |
|---------------------|---------------------------------------------|-----------------|-----|-----------------|------|
| F <sub>LFIOSC</sub> | Internal low-frequency oscillator frequency | 10 <sup>a</sup> | 33  | 90 <sup>a</sup> | KHz  |

a. Preliminary, pending characterization.

### 30.9.4 Hibernation Clock Source Specifications

Table 30-21. Hibernation Internal Low Frequency Oscillator Clock Characteristics

| Parameter              | Parameter Name                                          | Min | Nom | Max | Unit |
|------------------------|---------------------------------------------------------|-----|-----|-----|------|
| F <sub>HIBLFIOSC</sub> | Internal Low Frequency Hibernation oscillator frequency | 10  | 33  | 90  | KHz  |

Table 30-22. Hibernation External Oscillator (XOSC) Input Characteristics

| Parameter                         | Parameter Name               | Min | Nom    | Max | Unit |
|-----------------------------------|------------------------------|-----|--------|-----|------|
| F <sub>HIBXOSC</sub> <sup>a</sup> | Parallel resonance frequency | -   | 32.768 | -   | KHz  |

**Table 30-22. Hibernation External Oscillator (XOSC) Input Characteristics (continued)**

| Parameter                | Parameter Name                                                                               | Min          | Nom | Max               | Unit |
|--------------------------|----------------------------------------------------------------------------------------------|--------------|-----|-------------------|------|
| $C_1, C_2$               | External load capacitance on XOSC0, XOSC1 pins <sup>b</sup>                                  | 12           | -   | 24                | pF   |
| $C_{PKG}$                | Device package stray shunt capacitance <sup>b</sup>                                          | -            | 0.5 | -                 | pF   |
| $C_{PCB}$                | PCB stray shunt capacitance <sup>b</sup>                                                     | -            | 0.5 | -                 | pF   |
| $C_0$                    | Crystal shunt capacitance <sup>b</sup>                                                       | -            | 3   | -                 | pF   |
| $C_{SHUNT}$              | Total shunt capacitance <sup>b</sup>                                                         | -            | -   | 4                 | pF   |
| ESR                      | Crystal effective series resistance, OSCDRV = 0 <sup>c</sup>                                 | -            | -   | 50                | kΩ   |
|                          | Crystal effective series resistance, OSCDRV = 1 <sup>c</sup>                                 | -            | -   | 75                | kΩ   |
| DL                       | Oscillator output drive level                                                                | -            | -   | 0.25              | μW   |
| $T_{START}$              | Oscillator startup time, when using a crystal <sup>d</sup>                                   | -            | 600 | 1500 <sup>e</sup> | ms   |
| $V_{IH}^f$               | CMOS input high level, when using an external oscillator with Supply > 3.3 V                 | 2.64         | -   | -                 | V    |
|                          | CMOS input high level, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.3 V         | 0.8 * Supply | -   | -                 | V    |
| $V_{IL}^f$               | CMOS input low level, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.63 V         | -            | -   | 0.2 * Supply      | V    |
| $V_{HYS}^f$              | CMOS input buffer hysteresis, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.63 V | 360          | 960 | 1390              | mV   |
| DC <sub>HIBOSC_EXT</sub> | External single-Ended (Bypass) reference duty cycle                                          | 30           | -   | 70                | %    |

a. The HIB XOSC pins are non-failsafe and must follow the limits detailed in “Non-Power I/O Pins” on page 1927.

b. See information below table.

c. Crystal ESR specified by crystal manufacturer.

d. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

e. Only valid for recommended supply conditions. Measured with OSCDRV bit set (high drive strength enabled, 24 pF).

f. Specification is relative to the larger of  $V_{DD}$  or  $V_{BAT}$ .

The load capacitors added on the board,  $C_1$  and  $C_2$ , should be chosen such that the following equation is satisfied (see Table 30-22 on page 1916 for typical values).

- $C_L$  = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{PKG} + C_{PCB}$
- $C_{SHUNT} = C_{PKG} + C_{PCB} + C_0$  (total shunt capacitance seen across XOSC0, XOSC1)
- $C_{PKG}, C_{PCB}$  as measured across the XOSC0, XOSC1 pins excluding the crystal
- Clear the OSCDRV bit in the **Hibernation Control (HIBCTL)** register for  $C_{1,2} \leq 18$  pF; set the OSCDRV bit for  $C_{1,2} > 18$  pF.
- $C_0$  = Shunt capacitance of crystal specified by the crystal manufacturer

### 30.9.5 Main Oscillator Specifications

**Table 30-23. Main Oscillator Input Characteristics<sup>a</sup>**

| Parameter  | Parameter Name               | Min            | Nom | Max | Unit |
|------------|------------------------------|----------------|-----|-----|------|
| $F_{MOSC}$ | Parallel resonance frequency | 4 <sup>b</sup> | -   | 25  | MHz  |

Table 30-23. Main Oscillator Input Characteristics (continued)

| Parameter                       | Parameter Name                                                  | Min                    | Nom                | Max                    | Unit |
|---------------------------------|-----------------------------------------------------------------|------------------------|--------------------|------------------------|------|
| F <sub>REF_XTAL_BYPASS</sub>    | External clock reference (PLL in BYPASS mode) <sup>c</sup>      | 0                      | -                  | 120                    | MHz  |
| C <sub>1</sub> , C <sub>2</sub> | External load capacitance on OSC0, OSC1 pins <sup>d</sup>       | 12                     | -                  | 24                     | pF   |
| C <sub>PKG</sub>                | Device package stray shunt capacitance <sup>d</sup>             | -                      | 0.5                | -                      | pF   |
| C <sub>PCB</sub>                | PCB stray shunt capacitance <sup>d</sup>                        | -                      | 0.5                | -                      | pF   |
| C <sub>SHUNT</sub>              | Total shunt capacitance <sup>d</sup>                            | -                      | -                  | 4                      | pF   |
| ESR                             | Crystal effective series resistance, 4 MHz <sup>e</sup>         | -                      | -                  | 300                    | Ω    |
|                                 | Crystal effective series resistance, 6 MHz <sup>e</sup>         | -                      | -                  | 200                    | Ω    |
|                                 | Crystal effective series resistance, 8 MHz <sup>e</sup>         | -                      | -                  | 130                    | Ω    |
|                                 | Crystal effective series resistance, 12 MHz <sup>e</sup>        | -                      | -                  | 120                    | Ω    |
|                                 | Crystal effective series resistance, 16 MHz <sup>e</sup>        | -                      | -                  | 100                    | Ω    |
|                                 | Crystal effective series resistance, 25 MHz <sup>e</sup>        | -                      | -                  | 50                     | Ω    |
| DL                              | Oscillator output drive level <sup>f</sup>                      | -                      | OSC <sub>PWR</sub> | -                      | mW   |
| T <sub>START</sub>              | Oscillator startup time, when using a crystal <sup>g</sup>      | -                      | -                  | 18                     | ms   |
| V <sub>IH</sub>                 | CMOS input high level, when using an external oscillator        | 0.65 * V <sub>DD</sub> | -                  | V <sub>DD</sub>        | V    |
| V <sub>IL</sub>                 | CMOS input low level, when using an external oscillator         | GND                    | -                  | 0.35 * V <sub>DD</sub> | V    |
| V <sub>HYS</sub>                | CMOS input buffer hysteresis, when using an external oscillator | 150                    | -                  | -                      | mV   |
| DC <sub>OSC_EXT</sub>           | External clock reference duty cycle                             | 45                     | -                  | 55                     | %    |

a. Refer to Table 30-49 on page 1945 and Table 30-50 on page 1945 for additional Ethernet crystal requirements.

b. 5 MHz is the minimum when using the PLL.

c. Pending characterization

d. See information below table.

e. Crystal ESR specified by crystal manufacturer.

f.  $OSC_{PWR} = (2 * \pi * F_p * C_L * 2.5)^2 * ESR / 2$ . An estimation of the typical power delivered to the crystal is based on the C<sub>L</sub>, F<sub>p</sub> and ESR parameters of the crystal in the circuit as calculated by the OSC<sub>PWR</sub> equation. Ensure that the value calculated for OSC<sub>PWR</sub> does not exceed the crystal's drive-level maximum.

g. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

The load capacitors added on the board, C<sub>1</sub> and C<sub>2</sub>, should be chosen such that the following equation is satisfied (see Table 30-23 on page 1917 for typical values and Table 30-24 on page 1919 for detailed crystal parameter information).

- C<sub>L</sub> = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{SHUNT}$
- C<sub>SHUNT</sub> = C<sub>0</sub> + C<sub>PKG</sub> + C<sub>PCB</sub> (total shunt capacitance seen across OSC0, OSC1 crystal inputs)
- C<sub>PKG</sub>, C<sub>PCB</sub> = the mutual caps as measured across the OSC0, OSC1 pins excluding the crystal.
- C<sub>0</sub> = Shunt capacitance of crystal specified by the crystal manufacturer

Table 30-24 on page 1919 lists part numbers of crystals that have been simulated and confirmed to operate within the specifications in Table 30-23 on page 1917. Other crystals that have nearly identical crystal parameters can be expected to work as well.

In the table below, the crystal parameters labeled C0, C1 and L1 are values that are obtained from the crystal manufacturer. These numbers are usually a result of testing a relevant batch of crystals on a network analyzer. The parameters labeled ESR, DL and  $C_L$  are maximum numbers usually available in the data sheet for a crystal.

The table also includes three columns of Recommended Component Values. These values apply to system board components.  $C_1$  and  $C_2$  are the values in pico Farads of the load capacitors that should be put on each leg of the crystal pins to ensure oscillation at the correct frequency.  $R_s$  is the value in k $\Omega$  of a resistor that is placed in series with the crystal between the OSC1 pin and the crystal pin.  $R_s$  dissipates some of the power so the Max DI crystal parameter is not exceeded. Only use the recommended  $C_1$ ,  $C_2$ , and  $R_s$  values with the associated crystal part. The values in the table were used in the simulation to ensure crystal startup and to determine the worst case drive level (WC DI). The value in the WC DI column should not be greater than the Max DI Crystal parameter. The WC DI value can be used to determine if a crystal with similar parameter values but a lower Max DI value is acceptable.

**Table 30-24. Crystal Parameters**

| MFG     | MFG Part#                    | Holder   | PKG Size<br>(mm x mm) | Freq (MHz) | Crystal Spec<br>(Tolerance /<br>Stability) | Crystal Parameters |         |         |            |             |                     | Recommended<br>Component<br>Values |                     |                  | WC DI (μW) |
|---------|------------------------------|----------|-----------------------|------------|--------------------------------------------|--------------------|---------|---------|------------|-------------|---------------------|------------------------------------|---------------------|------------------|------------|

a. R<sub>S</sub> values as low as 0 Ohms can be used. Using a lower R<sub>S</sub> value will result in the WC DL to increase towards the Max DL of the crystal.

b. Although this ESR value is outside of the recommended crystal ESR maximum for this frequency, this crystal has been simulated to confirm proper operation and is valid for use with this device.

c. R<sub>S</sub> values as low as 500 Ohms can be used. Using a lower R<sub>S</sub> value will result in the WC DL to increase towards the Max DL of the crystal.

### 30.9.6 System Clock Specification with ADC Operation

**Table 30-25. System Clock Characteristics with ADC Operation**

| Parameter           | Parameter Name                                                                  | Min | Nom | Max | Unit |
|---------------------|---------------------------------------------------------------------------------|-----|-----|-----|------|
| $F_{\text{sysadc}}$ | System clock frequency when the ADC module is operating (when PLL is bypassed). | -   | 16  | -   | MHz  |

### 30.9.7 System Clock Specification with USB Operation

**Table 30-26. System Clock Characteristics with USB Operation**

| Parameter           | Parameter Name                                                                                                                          | Min | Nom | Max | Unit |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------|-----|-----|-----|------|
| $F_{\text{sysusb}}$ | System clock frequency when the USB module is operating (note that MOSC must be the clock source, either with or without using the PLL) | 30  | -   | -   | MHz  |

## 30.10 Sleep Modes

The following tables can be used to calculate the maximum wake time from Sleep or Deep Sleep depending on the specific application. Depending on the application configuration, each of the parameters, except for  $T_{\text{FLASH}}$ , add sequential latency to the wake time. Flash restoration happens in parallel to the other wake processes and its wake time is normally absorbed by the other latencies. As an example, the wake time for a device in Deep Sleep, with the PIOSC and PLL turned off and the Flash and SRAM in low power mode is calculated as follows:

$$\text{Wake Time} = T_{\text{PIOSCDs}} + T_{\text{PLLDS}} + T_{\text{SRAMLPS}}$$

$T_{\text{FLASH}}$  does not contribute to this equation since all other parameters are greater in value.

Note that in Sleep mode the wake time due to a clock source is zero because the device uses the same clock configuration in Run mode; thus, there is no latency involved with respect to the clocks.

**Table 30-27. Wake from Sleep Characteristics**

| Parameter No | Parameter             | Parameter Name                                                           | Min | Nom | Max              | Unit |
|--------------|-----------------------|--------------------------------------------------------------------------|-----|-----|------------------|------|
| D1           | $T_{\text{PIOSC}}$    | Time to restore PIOSC as System Clock in Sleep mode                      | -   | -   | N/A <sup>a</sup> | μs   |
| D2           | $T_{\text{MOSC}}$     | Time to restore MOSC as System Clock in Sleep mode                       | -   | -   | N/A <sup>b</sup> | μs   |
| D3           | $T_{\text{PLL}}$      | Time to restore PLL as System Clock in Sleep mode                        | -   | -   | N/A <sup>c</sup> | μs   |
| D4           | $T_{\text{LDO}}$      | Time to restore LDO to 1.2 V in Sleep mode                               | -   | -   | 39               | μs   |
| D5           | $T_{\text{FLASH}}$    | Time to restore Flash to active state from low power state in Sleep mode | -   | -   | 5                | μs   |
| D6           | $T_{\text{SRAMLPS}}$  | Time to restore SRAM to active state from low power state in Sleep mode  | -   | -   | 15               | μs   |
| D7           | $T_{\text{SRAMSTBY}}$ | Time to restore SRAM to active state from standby state in Sleep mode    | -   | -   | 15               | μs   |

a. Because the PIOSC is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

b. Because the MOSC is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

c. Because the PLL is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

**Table 30-28. Wake from Deep Sleep Characteristics**

| Parameter No | Parameter        | Parameter Name                                             | Min | Nom | Max                                                                          | Unit                                 |
|--------------|------------------|------------------------------------------------------------|-----|-----|------------------------------------------------------------------------------|--------------------------------------|
| D8           | $T_{PIOSCDs}$    | Time to restore PIOSC as System Clock in Deep Sleep Mode   | -   | -   | 14                                                                           | Deep Sleep Clock Cycles <sup>a</sup> |
| D9           | $T_{MOSCDs}$     | Time to restore MOSC as System Clock in Deep Sleep Mode    | -   | -   | 18                                                                           | ms                                   |
| D10          | $T_{PLLDs}$      | Time to restore PLL as System Clock in Deep Sleep Mode     | -   | -   | 1 cycle of Deep Sleep Clock + 512 cycles of PLL reference Clock <sup>a</sup> | clocks                               |
| D11          | $T_{LDODs}$      | Time to restore LDO to 1.2 V in Deep Sleep Mode            | -   | -   | 39                                                                           | $\mu s$                              |
| D12          | $T_{FLASHLPDs}$  | Time to restore Flash to active state from low power state | -   | -   | 5                                                                            | $\mu s$                              |
| D13          | $T_{SRAMLpDs}$   | Time to restore SRAM to active state from low power state  | -   | -   | 15                                                                           | $\mu s$                              |
| D14          | $T_{SRAMSTBYDs}$ | Time to restore SRAM to active state from standby state    | -   | -   | 15                                                                           | $\mu s$                              |

a. Deep Sleep Clock can vary. See page 285 for the Deep Sleep Clock options.

## 30.11 Hibernation Module

The Hibernation module requires special system implementation considerations because it is intended to power down all other sections of its host device, refer to “Hibernation Module” on page 531.

**Table 30-29. Hibernation Module Battery Characteristics**

| Parameter                 | Parameter Name                             | Min | Nominal | Max              | Unit       |
|---------------------------|--------------------------------------------|-----|---------|------------------|------------|
| $V_{BAT}$                 | Battery supply voltage                     | 1.8 | 3.0     | 3.6 <sup>a</sup> | V          |
| $V_{BATRMP}$ <sup>b</sup> | $V_{BAT}$ battery supply voltage ramp time | 0   | -       | 0.7              | V/ $\mu s$ |
| $V_{LOWBAT}$              | Low battery detect voltage, VBATSEL=0x0    | 1.8 | 1.9     | 2.0              | V          |
|                           | Low battery detect voltage, VBATSEL=0x1    | 2.0 | 2.1     | 2.2              | V          |
|                           | Low battery detect voltage, VBATSEL=0x2    | 2.2 | 2.3     | 2.4              | V          |
|                           | Low battery detect voltage, VBATSEL=0x3    | 2.4 | 2.5     | 2.6              | V          |

a. To ensure proper functionality, any voltage input higher than  $V_{BAT}$  Max, must be connected through a diode.

b. For recommended  $V_{BAT}$  RC circuit values, refer to the diagrams located in “Hibernation Clock Source” on page 535.

**Table 30-30. Hibernation Module Characteristics**

| Parameter No | Parameter           | Parameter Name                                                         | Min | Nom                                        | Max | Unit                     |
|--------------|---------------------|------------------------------------------------------------------------|-----|--------------------------------------------|-----|--------------------------|
| H1           | $T_{WAKE}$          | WAKE assertion time                                                    | 100 | -                                          | -   | ns                       |
| H2           | $T_{WAKE\_TO\_HIB}$ | WAKE assert to HIB desassert (wake up time)                            | -   | -                                          | 1   | Hibernation clock period |
| H3           | $T_{VDD\_RAMP}$     | $V_{DD}$ ramp to 3.0 V                                                 | -   | Depends on characteristics of power supply | -   | $\mu s$                  |
| H4           | $T_{VDD\_CODE}$     | $V_{DD}$ at 3.0 V to internal POR deassert; first instruction executes | -   | -                                          | 500 | $\mu s$                  |

**Table 30-30. Hibernation Module Characteristics (continued)**

| Parameter No | Parameter            | Parameter Name                                                                                           | Min | Nom | Max | Unit |
|--------------|----------------------|----------------------------------------------------------------------------------------------------------|-----|-----|-----|------|
| H5           | DC <sub>RTCCLK</sub> | Duty cycle for RTCCLK output signal, when using a 32.768-kHz crystal                                     | 40  | -   | 60  | %    |
|              |                      | Duty cycle for RTCCLK output signal, when using a 32.768-kHz external single-ended (bypass) clock source | 30  | -   | 70  | %    |

**Table 30-31. Hibernation Module Tamper I/O Characteristics**

| Parameter         | Parameter Name                                          | Min                   | Nominal | Max | Unit |
|-------------------|---------------------------------------------------------|-----------------------|---------|-----|------|
| R <sub>TPU</sub>  | TMPRn pull-up resistor                                  | -                     | 4.4     | -   | MΩ   |
| T <sub>SP</sub>   | TMPRn pulse width with short glitch filter              | 62                    | -       | -   | μs   |
| T <sub>LP</sub>   | TMPRn pulse width with long glitch filter               | 94                    | -       | -   | ms   |
| T <sub>NMIS</sub> | TMPRn assertion to NMI (short glitch filter)            | -                     | -       | 95  | μs   |
| T <sub>NMIL</sub> | TMPRn assertion to NMI (long glitch filter)             | -                     | -       | 94  | ms   |
| V <sub>IH</sub>   | TMPRn high-level input voltage when operating from VBAT | V <sub>BAT</sub> *0.8 | -       | -   | V    |

**Figure 30-15. Hibernation Module Timing**

## 30.12 Flash Memory

**Table 30-32. Flash Memory Characteristics**

| Parameter            | Parameter Name                                                                                                  | Min     | Nom | Max | Unit   |
|----------------------|-----------------------------------------------------------------------------------------------------------------|---------|-----|-----|--------|
| PE <sub>CYC</sub>    | Number of program/erase cycles <sup>a</sup>                                                                     | 100,000 | -   | -   | cycles |
| T <sub>RET</sub>     | Data retention with 100% power-on hours at T <sub>J</sub> =85°C                                                 | 20      | -   | -   | years  |
| T <sub>RET_EXT</sub> | Data retention with 10% power-on hours at T <sub>J</sub> =125°C and 90% power-on hours at T <sub>J</sub> =100°C | 11      | -   | -   | years  |
| T <sub>PROG64</sub>  | Program time for double-word-aligned (64 bits) data <sup>b</sup>                                                | 30      | 50  | 300 | μs     |
| T <sub>ERASE</sub>   | Page erase time, <1k cycles                                                                                     | -       | 8   | 15  | ms     |
|                      | Page erase time, 10k cycles                                                                                     | -       | 15  | 40  | ms     |
|                      | Page erase time, 100k cycles                                                                                    | -       | 75  | 500 | ms     |

Table 30-32. Flash Memory Characteristics (continued)

| Parameter | Parameter Name               | Min | Nom | Max  | Unit |
|-----------|------------------------------|-----|-----|------|------|
| $T_{ME}$  | Mass erase time, <1k cycles  | -   | 10  | 25   | ms   |
|           | Mass erase time, 10k cycles  | -   | 20  | 70   | ms   |
|           | Mass erase time, 100k cycles | -   | 300 | 2500 | ms   |

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

b. If programming fewer than 64 bits of data, the programming time is the same. For example, if only 32 bits of data need to be programmed, the other 32 bits are masked off.

## 30.13 EEPROM

Table 30-33. EEPROM Characteristics<sup>a</sup>

| Parameter         | Parameter Name                                                                                                                                                | Min     | Nom | Max               | Unit          |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-----|-------------------|---------------|
| $EPE_{CYC}^b$     | Number of mass program/erase cycles of a single word <sup>c</sup>                                                                                             | 500,000 | -   | -                 | cycles        |
| $ET_{RET}$        | Data retention with 100% power-on hours at $T_J=85^{\circ}C$                                                                                                  | 20      | -   | -                 | years         |
| $ET_{RET\_EXTMP}$ | Data retention with 10% power-on hours at $T_J=125^{\circ}C$ and 90% power-on hours at $T_J=100^{\circ}C$                                                     | 11      | -   | -                 | years         |
| $ET_{PROG}$       | Program time for 32 bits of data with memory space available                                                                                                  | -       | 110 | 600               | $\mu s$       |
|                   | Program time for 32 bits of data in which a copy to the copy buffer is required, the copy buffer has space and less than 10% of EEPROM endurance used         | -       | 30  | -                 | ms            |
|                   | Program time for 32 bits of data in which a copy to the copy buffer is required, the copy buffer has space and greater than 90% of EEPROM endurance used      | -       | -   | 900               | ms            |
|                   | Program time for 32 bits of data in which a copy of the copy buffer is required, the copy buffer requires an erase and less than 10% of EEPROM endurance used | -       | 60  | -                 | ms            |
|                   | Program time for 32 bits of data a copy to the copy buffer is required, the copy buffer requires an erase and greater than 90% of EEPROM endurance used       | -       | -   | 1800              | ms            |
| $ET_{READ}$       | Read access time                                                                                                                                              | -       | -   | -                 | system clocks |
| $ET_{ME}$         | Mass erase time, <1k cycles                                                                                                                                   | -       | 8   | 15                | ms            |
|                   | Mass erase time, 10k cycles                                                                                                                                   | -       | 15  | 40                | ms            |
|                   | Mass erase time, 100k cycles                                                                                                                                  | -       | 75  | 500               | ms            |
| $ET_{PORDLY}$     | EEPROM recovery Power-On Reset delay <sup>d</sup>                                                                                                             | -       | -   | 2000 <sup>e</sup> | ms            |

a. Because the EEPROM operates as a background task and does not prevent the CPU from executing from Flash memory, the operation will complete within the maximum time specified provided the EEPROM operation is not stalled by a Flash memory program or erase operation.

b. One word can be written more than 500K times, but these writes impact the endurance of the words in the meta-block that the word is within. Different words can be written such that any or all words can be written more than 500K times when write counts per word stay about the same. See the section called "Endurance" on page 619 for more information.

c. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

d. This parameter applies only in situations where a power-down or brown-out event occurs during an EEPROM program or erase operation. For all other sequences, there is no impact to normal Power-On Reset (POR) timing. This delay is in addition to other POR delays.

e. The maximum Power-On Reset delay increases as the EEPROM memory ages towards its endurance limit.

## 30.14 Input/Output Pin Characteristics

**Note:** All GPIO signals are 3.3-V tolerant, except for PB1 (USB0VBUS) which is 5-V tolerant. See “Signal Description” on page 742 for more information on GPIO configuration.

Two types of pads are provided on the device:

- Fast GPIO pads: These pads provide variable, programmable drive strength and optimized voltage output levels.
- Slow GPIO pads: These pads provide 2-mA drive strength and are designed to be sensitive to voltage inputs. The following GPIOs port pins are designed with Slow GPIO Pads:
  - PJ1

**Note:** Port pins PL6 and PL7 operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIODR**.

**Note:** Port pins PM[7:4] operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIODR12R** register, apply to these port pins.

**Table 30-34. Fast GPIO Module Characteristics**<sup>abcd</sup>

| Parameter              | Parameter Name                                                                                                                          | Min  | Nom  | Max   | Unit |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|------|------|-------|------|
| C <sub>LGPIO</sub>     | Capacitive loading for measurements given in this table <sup>e</sup>                                                                    | -    | -    | 50    | pF   |
| R <sub>GPIOPU</sub>    | Fast GPIO internal pull-up resistor <sup>f</sup>                                                                                        | 12.1 | 16.0 | 20.2  | kΩ   |

|                        | Fast GPIO rise time, 8-mA drive with slew rate control <sup>h</sup>                                                                     |      | 3.77 | 5.76  | ns   |
|                        | Fast GPIO rise time, 10-mA drive <sup>h</sup>                                                                                           |      | 1.98 | 3.22  | ns   |
|                        | Fast GPIO rise time, 12-mA drive <sup>h</sup>                                                                                           |      | 1.75 | 2.9   | ns   |

**Table 30-34. Fast GPIO Module Characteristics (continued)**

| Parameter   | Parameter Name                                                      | Min | Nom  | Max  | Unit |
|-------------|---------------------------------------------------------------------|-----|------|------|------|
| $T_{GPIOF}$ | Fast GPIO fall time, 2-mA drive <sup>i</sup>                        | -   | 10.3 | 16.5 | ns   |
|             | Fast GPIO fall time, 4-mA drive <sup>i</sup>                        |     | 5.15 | 8.29 | ns   |
|             | Fast GPIO fall time, 8-mA drive <sup>i</sup>                        |     | 2.58 | 4.16 | ns   |
|             | Fast GPIO fall time, 8-mA drive with slew rate control <sup>i</sup> |     | 3.54 | 5.55 | ns   |
|             | Fast GPIO fall time, 10-mA drive <sup>i</sup>                       |     | 2.07 | 3.34 | ns   |
|             | Fast GPIO fall time, 12-mA drive <sup>i</sup>                       |     | 1.73 | 2.78 | ns   |

- a.  $V_{DD}$  must be within the range specified in Table 30-6 on page 1902.
- b. Leakage and Injection current characteristics specified in this table also apply to XOSC0 and XOSC1 inputs.
- c. Note that for the ADC's external reference inputs, care must be taken to avoid a current limiting resistor (refer to  $I_{VREF}$  spec in Table 30-44 on page 1935)
- d. I/O pads should be protected if at any point the IO voltage has a possibility of going outside the limits shown in the table. If the part is unpowered, the IO pad Voltage or Current must be limited (as shown in this table) to avoid powering the part through the IO pad, causing potential irreversible damage.
- e. Refer to individual peripheral sections for specific loading information.
- f. This value includes all GPIO except for port pins PL6 and PL7.
- g. The leakage current is measured with  $V_{IN}$  applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pull-up/pull-down resistor is disabled.
- h. Time measured from 20% to 80% of  $V_{DD}$ .
- i. Time measured from 80% to 20% of  $V_{DD}$ .

**Table 30-35. Slow GPIO Module Characteristics<sup>abc</sup>**

| Parameter    | Parameter Name                                                                                                        | Min  | Nom  | Max  | Unit       |
|--------------|-----------------------------------------------------------------------------------------------------------------------|------|------|------|------------|
| $C_{LGPIO}$  | Capacitive loading for measurements given in this table <sup>d</sup>                                                  | -    | -    | 50   | pF         |
| $R_{GPIOPU}$ | Slow GPIO internal pull-up resistor                                                                                   | 13.8 | 20.0 | 31.4 | k $\Omega$ |
| $R_{GPIOPD}$ | Slow GPIO internal pull-down resistor                                                                                 | 13.0 | 20.5 | 35.5 | k $\Omega$ |
| $I_{LKG+}$   | Slow GPIO input leakage current, $0 V \leq V_{IN} \leq V_{DD}$ , GPIO pins <sup>e</sup>                               | -    | -    | 3.25 | nA         |
|              | Slow GPIO input leakage current, $0 V < V_{IN} \leq V_{DD}$ , GPIO pins configured as ADC or analog comparator inputs | -    | -    | 3.25 | nA         |
| $I_{INJ-}$   | DC injection current, $V_{IN} \leq 0 V$                                                                               | -    | -    | 3.42 | $\mu A$    |
| $T_{GPIOR}$  | Slow GPIO rise time, 2-mA drive <sup>f</sup>                                                                          | -    | 19.3 | 29.8 | ns         |
| $T_{GPIOF}$  | Slow GPIO fall time, 2-mA drive <sup>g</sup>                                                                          | -    | 12.8 | 21.1 | ns         |

- a.  $V_{DD}$  must be within the range specified in Table 30-6 on page 1902.
- b.  $V_{IN}$  must be within the range specified in Table 30-1 on page 1900. Leakage current outside of this maximum voltage is not guaranteed and can result in permanent damage of the device.
- c. To avoid potential damage to the part, either the voltage or current on the non-Power, non-WAKE input/outputs should be limited externally as shown in this table.
- d. Refer to individual peripheral sections for specific loading information.
- e. The leakage current is measured with  $V_{IN}$  applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pull-up/pull-down resistor is disabled.
- f. Time measured from 20% to 80% of  $V_{DD}$ .
- g. Time measured from 80% to 20% of  $V_{DD}$ .

### 30.14.1 Types of I/O Pins and ESD Protection

**Caution** – All device I/Os pins, except for PB1, are NOT 5V tolerant; voltages in excess of the limits shown in Table 30-6 on page 1902 can permanently damage the device. PB1 is used for the USB's USB0VBUS signal, which requires a 5-V input.

#### 30.14.1.1 Hibernate WAKE pin

The Hibernate WAKE pin uses ESD protection, similar to the one shown in Figure 30-16 on page 1927. This ESD protection prevents a direct path between this pad and any power supply rails in the device. The WAKE pad input voltage should be kept inside the maximum ratings specified in Table 30-1 on page 1900 to ensure current leakage and current injections are within acceptable range. Current leakages and current injection for these pins are specified in Table 30-36 on page 1927.

**Figure 30-16. ESD Protection**

**Table 30-36. Pad Voltage/Current Characteristics for Hibernate WAKE Pin<sup>ab</sup>**

| Parameter  | Parameter Name                                                   | Min | Nom | Max  | Unit    |
|------------|------------------------------------------------------------------|-----|-----|------|---------|
| $I_{LKG+}$ | Positive IO leakage for $V_{DD} \leq V_{IN} \leq V_{BAT} + 0.3V$ | -   | -   | 300  | nA      |
| $I_{LKG-}$ | Negative IO leakage for $-0.3V \leq V_{IN} \leq 0V^c$            | -   | -   | 43.3 | $\mu A$ |
| $I_{INJ+}$ | Max positive injection if not voltage protected <sup>d</sup>     | -   | -   | 2    | mA      |
| $I_{INJ-}$ | Max negative injection if not voltage protected <sup>d</sup>     | -   | -   | -0.5 | mA      |

a.  $V_{IN}$  must be within the range specified in Table 30-1 on page 1900. Leakage current outside of this maximum voltage is not guaranteed and can result in permanent damage of the device.

b. VDD must be within the range specified in Table 30-6 on page 1902.

c. Leakage outside the minimum range (-0.3V) is unbounded and must be limited to  $I_{INJ-}$  using an external resistor.

d. If the I/O pad is not voltage limited, it should be current limited (to  $I_{INJ+}$  and  $I_{INJ-}$ ) if there is any possibility of the pad voltage exceeding the  $V_{IO}$  limits (including transient behavior during supply ramp up, or at any time when the part is unpowered).

#### 30.14.1.2 Non-Power I/O Pins

Most non-power I/Os (with the exception of the I/O pad for Hibernate WAKE input) have ESD protection as shown in Figure 30-17 on page 1928.

These I/Os have an ESD clamp to ground and a diode connection to the corresponding power supply rail. The voltage and current of these I/Os should follow the specifications in Table 30-37 on page 1928 to prevent potential damage to the device. In addition, it is recommended that the ADC external reference specifications in Table 30-44 on page 1935 be adhered to prevent any gain error.

Figure 30-17. ESD Protection for Non-Power Pins (Except  $\overline{\text{WAKE}}$  Signal)Table 30-37. Non-Power I/O Pad Voltage/Current Characteristics<sup>abc</sup>

| Parameter  | Parameter Name                                                         | Min  | Nom      | Max          | Unit          |
|------------|------------------------------------------------------------------------|------|----------|--------------|---------------|
| $V_{IO}^d$ | IO pad voltage limits if voltage protected                             | -0.3 | $V_{DD}$ | $V_{DD}+0.3$ | V             |
| $I_{LKG+}$ | Positive IO leakage for $V_{DD} \leq V_{IN} \leq V_{IO} \text{ MAX}^e$ | -    | -        | 400          | nA            |
| $I_{LKG-}$ | Negative IO leakage for $V_{IO} \text{ MIN} \leq V_{IN} \leq 0V^e$     | -    | -        | 60           | $\mu\text{A}$ |
| $I_{INJ+}$ | Max positive injection if not voltage protected <sup>f</sup>           | -    | -        | 2            | mA            |
| $I_{INJ-}$ | Max negative injection if not voltage protected <sup>f</sup>           | -    | -        | -0.5         | mA            |

- a. To avoid potential damage to the part, either the voltage or current on the non-Power, non- $\overline{\text{WAKE}}$  input/outputs should be limited externally as shown in this table.
- b. Note that for the ADC's external reference inputs, care must be taken to avoid a current limiting resistor (refer to IVREF spec in Table 30-44 on page 1935)
- c. I/O pads should be protected if at any point the IO voltage has a possibility of going outside the limits shown in the table. If the part is unpowered, the IO pad Voltage or Current must be limited (as shown in this table) to avoid powering the part through the IO pad, causing potential irreversible damage.
- d. The Hibernate XOSC pins are non-failsafe and should follow the limits for  $V_{IO}$  with respect to both  $V_{DD}$  and  $V_{BAT}$ . Thus  $V_{IO}$  for the HIB XOSC pins should also fall within a MIN of -0.3 and a MAX of  $V_{BAT} + 0.3$ .
- e. MIN and MAX leakage current for the case when the I/O is voltage protected to  $V_{IO} \text{ Min}$  or  $V_{IO} \text{ Max}$ .
- f. If the I/O pad is not voltage limited, it should be current limited (to  $I_{INJ+}$  and  $I_{INJ-}$ ) if there is any possibility of the pad voltage exceeding the  $V_{IO}$  limits (including transient behavior during supply ramp up, or at any time when the part is unpowered).

## 30.15 External Peripheral Interface (EPI)

Table 30-38. EPI Interface Load Conditions

| Signals                               | Load Value ( $C_L$ ) |
|---------------------------------------|----------------------|
| EPI0S[35:0] SDRAM interface           | 30 pF                |
| EPI0S[35:0] General-Purpose interface |                      |
| EPI0S[35:0] Host-Bus interface        |                      |
| EPI0S[35:0] PSRAM interface           | 40 pF                |

When the EPI module is in SDRAM mode, EPI CLK must be configured to 12 mA. The EPI data bus can be configured to 8 mA. Table 30-39 on page 1929 shows the rise and fall times in SDRAM mode. When the EPI module is in Host-Bus or General-Purpose mode, the values in "Input/Output Pin Characteristics" on page 1925 should be used.

**Table 30-39. EPI SDRAM Characteristics**

| Parameter    | Parameter Name                               | Condition                  | Min | Nom | Max | Unit |
|--------------|----------------------------------------------|----------------------------|-----|-----|-----|------|
| $T_{SDRAMR}$ | EPI Rise Time (from 20% to 80% of $V_{DD}$ ) | 12-mA drive, $C_L = 30$ pF | -   | 2   | 3   | ns   |
| $T_{SDRAMF}$ | EPI Fall Time (from 80% to 20% of $V_{DD}$ ) | 12-mA drive, $C_L = 30$ pF | -   | 2   | 3   | ns   |

**Table 30-40. EPI SDRAM Interface Characteristics<sup>a</sup>**

| Parameter No | Parameter | Parameter Name         | Min   | Nom | Max | Unit    |
|--------------|-----------|------------------------|-------|-----|-----|---------|
| E1           | $T_{CK}$  | SDRAM Clock period     | 16.67 | -   | -   | ns      |
| E2           | $T_{CH}$  | SDRAM Clock high time  | 8.33  | -   | -   | ns      |
| E3           | $T_{CL}$  | SDRAM Clock low time   | 8.33  | -   | -   | ns      |
| E4           | $T_{COV}$ | CLK to output valid    | -     | -   | 4   | ns      |
| E5           | $T_{COI}$ | CLK to output invalid  | -     | -   | 4   | ns      |
| E6           | $T_{COT}$ | CLK to output tristate | -     | -   | 4   | ns      |
| E7           | $T_S$     | Input set up to CLK    | 8.5   | -   | -   | ns      |
| E8           | $T_H$     | CLK to input hold      | 0     | -   | -   | ns      |
| E9           | $T_{PU}$  | Power-up time          | 100   | -   | -   | μs      |
| E10          | $T_{RP}$  | Precharge all banks    | 20    | -   | -   | ns      |
| E11          | $T_{RFC}$ | Auto refresh           | 66    | -   | -   | ns      |
| E12          | $T_{MRD}$ | Program mode register  | 2     | -   | -   | EPI CLK |

a. The EPI SDRAM interface must use 12-mA drive.

**Figure 30-18. SDRAM Initialization and Load Mode Register Timing**

- Notes:
1. If CS is high at clock high time, all applied commands are NOP.
  2. The **Mode** register may be loaded prior to the auto refresh cycles if desired.
  3. JEDEC and PC100 specify three clocks.
  4. Outputs are guaranteed High-Z after command is issued.

**Table 30-42. EPI General-Purpose Interface Characteristics**

| Parameter No | Parameter   | Parameter Name                                                  | Min   | Nom | Max | Unit |
|--------------|-------------|-----------------------------------------------------------------|-------|-----|-----|------|
| E25          | $T_{CK}$    | General-Purpose Clock period                                    | 16.67 | -   | -   | ns   |
| E26          | $T_{CH}$    | General-Purpose Clock high time                                 | 8.33  | -   | -   | ns   |
| E27          | $T_{CL}$    | General-Purpose Clock low time                                  | 8.33  | -   | -   | ns   |
| E28          | $T_{ISU}$   | Input signal set up time to rising clock edge                   | 8.50  | -   | -   | ns   |
| E29          | $T_{IH}$    | Input signal hold time from rising clock edge                   | 0     | -   | -   | ns   |
| E30          | $T_{DV}$    | Falling clock edge to output valid                              | -     | -   | 4   | ns   |
| E31          | $T_{DI}$    | Falling clock edge to output invalid                            | -     | -   | 4   | ns   |
| E32          | $T_{RDYSU}$ | iRDY assertion or deassertion set up time to falling clock edge | 8.5   | -   | -   | ns   |

**Figure 30-25. General-Purpose Mode Read and Write Timing**

**Note:** This figure illustrates accesses where the FRM50 bit is clear, the FRMCNT field is 0x0 and the WR2CYC bit is clear.

**Table 30-43. EPI PSRAM Interface Characteristics**

| Parameter No | Parameter           | Parameter Name                                                             | Min             | Nom | Max | Unit |
|--------------|---------------------|----------------------------------------------------------------------------|-----------------|-----|-----|------|
| E33          | $T_{\text{EPICLK}}$ | EPI_CLK period                                                             | 18 <sup>a</sup> | -   | -   | ns   |
| E34          | $T_{\text{RTFT}}$   | EPI_CLK rise or fall time                                                  | -               | -   | 1.8 | ns   |
| E35          | $T_{\text{OV}}$     | Falling EPI_CLK to Address/Write Data or Control output valid <sup>b</sup> | 4.5             | -   | 20  | ns   |
| E36          | $T_{\text{HT}}$     | Falling EPI_CLK to Address/Write Data or Control hold time <sup>b</sup>    | 2               | -   | -   | ns   |
| E37          | $T_{\text{SUP}}$    | Read data setup time from EPI_CLK rising                                   | -               | -   | 9   | ns   |
| E38          | $T_{\text{DH}}$     | Read data output hold from EPI_CLK rising                                  | 0               | -   | -   | ns   |
| E39          | $T_{\text{IRV}}$    | iRDY setup time                                                            | -               | -   | 9   | ns   |
| E40          | $T_{\text{IRH}}$    | iRDY hold time                                                             | -               | -   | 9   | ns   |

a. If the iRDY signal is being used with PSRAM, then the minimum allowed EPI\_CLK period is 19 ns.

b. Control output includes WRn, RDn, OEn, BSELn, ALE, and CSn.

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|-------|-----|-------|
| SNR <sub>S</sub>   | Signal-to-noise-ratio, Single-ended input, V <sub>ADCIN</sub> :<br>-20dB FS, 1KHz <sup>y</sup>                                                                       | 60  | 65    | -   | dB    |
| SDR <sub>S</sub>   | Signal-to-distortion ratio, Single-ended input,<br>V <sub>ADCIN</sub> : -3dB FS, 1KHz <sup>uv</sup>                                                                  | 70  | 72    | -   | dB    |
| SNDR <sub>S</sub>  | Signal-to-Noise+Distortion ratio, Single-ended<br>input, V <sub>ADCIN</sub> : -3dB FS, 1KHz <sup>ywx</sup>                                                           | 60  | 63    | -   | dB    |
| TEMPERATURE SENSOR |                                                                                                                                                                      |     |       |     |       |
| V <sub>TSENS</sub> | Temperature sensor voltage, junction<br>temperature 25 °C                                                                                                            | -   | 1.633 | -   | V     |
| S <sub>TSENS</sub> | Temperature sensor slope at:<br>-40°C to 85 °C ambient (industrial temperature<br>part)<br>-40°C to 105 °C ambient (extended temperature<br>part)                    | -   | -13.3 | -   | mV/°C |
| E <sub>TSENS</sub> | Temperature sensor accuracy at:<br>-40°C to 85 °C ambient (industrial temperature<br>part)<br>-40°C to 105 °C ambient (extended temperature<br>part)<br><sup>z</sup> | -   | -     | ±5  | °C    |

a. Values are at V<sub>REF+</sub> = 3.3V, F<sub>ADC</sub> = 16 MHz unless otherwise noted.

b. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk. Unexpected results can occur if a switching digital I/O is placed adjacent to an ADC input channel or voltage reference input. In addition, analog signals configured adjacent to ADC input channels or reference inputs must meet the R<sub>ADC</sub> equivalent input resistance given in this table and must be band-limited to 100 kHz or lower.

c. Two capacitors in parallel. Note that these capacitors should be as close to the die as possible.

d. Assumes external filtering network between VREFA+ and VREFA- as shown in Figure 30-28 on page 1941. External reference noise level must be under 12bit (-74 dB) of Full Scale input, over input bandwidth, measured at VREFA+ - VREFA-.

e. Internal reference is connected directly between V<sub>DDA</sub> and GNDA (VREFi = V<sub>DDA</sub> - GNDA). In this mode, E<sub>O</sub>, E<sub>G</sub>, E<sub>T</sub>, and dynamic specifications are adversely affected due to internal voltage drop and noise on V<sub>DDA</sub> and GNDA. Internal reference voltage is selected when VREF field in the **ADCCTL** register is 0x0.

f. V<sub>ADCIN</sub> = V<sub>INP</sub> - V<sub>INN</sub>

g. With signal common mode as V<sub>DDA</sub>/2.

h. With signal common mode as (V<sub>REF+</sub> + V<sub>REF-</sub>)/2.

i. This parameter is defined as the average of the differential inputs.

j. As shown in Figure 30-29 on page 1941, R<sub>ADC</sub> is the total equivalent resistance in the input line all the way up to the sampling node at the input of the ADC.

k. See "System Clock Specification with ADC Operation" on page 1921 for full ADC clock frequency specification.

l. ADC conversion time (T<sub>c</sub>) includes the ADC sample time (T<sub>s</sub>).

m. Low noise environment is assumed in order to obtain values close to spec. Board must have good ground isolation between analog and digital grounds, a clean reference voltage is assumed, and input signal must be bandlimited to Nyquist bandwidth. No anti-aliasing filter is provided internally.

n. ADC static measurements taken by averaging over several samples. At least 20-sample averaging is assumed to obtain expected typical or maximum spec values.

o. 12-bit DNL

p. Gain error is measured at max code after compensating for offset. Gain error is equivalent to "Full Scale Error." It can be given in % of slope error, or in LSB, as done here.

q. Total Unadjusted Error is the maximum error at any one code versus the ideal ADC curve. It includes all other errors (offset error, gain error and INL) at any given ADC code.

- r. A low noise environment is assumed in order to obtain values close to spec. The board must have good ground isolation between analog and digital grounds and a clean reference voltage. The input signal must be band-limited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- s. ADC dynamic characteristics are measured using low-noise board design, with low-noise reference voltage ( < -74dB noise level in signal BW) and low-noise analog supply voltage. Board noise and ground bouncing couple into the ADC and affect dynamic characteristics. Clean external reference must be used to achieve shown specs.
- t. Differential signal with correct common mode, applied between two ADC inputs.
- u. SDR = -THD in dB.
- v. For higher frequency inputs, degradation in SDR should be expected.
- w. SNDR = S/(N+D) = SINAD (in dB)
- x. Effective number of bits (ENOB) can be calculated from SNDR: ENOB = (SNDR - 1.76) / 6.02.
- y. Single ended inputs are more sensitive to board and trace noise than differential inputs; SNR and SNDR measurements on single-ended inputs are highly dependent on how clean the test set-up is. If the input signal is not well-isolated on the board, higher noise than specified could potentially be seen at the ADC output.
- z. Note that this parameter does not include ADC error.

**Table 30-45. ADC Electrical Characteristics for ADC at 2 Msps<sup>ab</sup>**

| Parameter                        | Parameter Name                                                                                                   | Min                                         | Nom                      | Max                                               | Unit |

**Table 30-45. ADC Electrical Characteristics for ADC at 2 Msps (continued)**

| Parameter          | Parameter Name                                                                 | Min | Nom | Max | Unit |
|--------------------|--------------------------------------------------------------------------------|-----|-----|-----|------|
| E <sub>TSENS</sub> | Temperature sensor accuracy, -40 °C to 85 °C, ambient temperature <sup>z</sup> | -   | -   | ±5  | °C   |

- a. Values are at  $V_{REF+} = 3.3V$ ,  $F_{ADC} = 32$  MHz unless otherwise noted.
- b. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk. Unexpected results can occur if a switching digital I/O is placed adjacent to an ADC input channel or voltage reference input. In addition, analog signals configured adjacent to ADC input channels or reference inputs must meet the  $R_{ADC}$  equivalent input resistance given in this table and must be band-limited to 100 kHz or lower.
- c. Two capacitors in parallel. Note that these capacitors should be as close to the die as possible.
- d. Assumes external filtering network between VREF+ and VREF- as shown in Figure 30-28 on page 1941. External reference noise level must be under 12bit (-74 dB) of Full Scale input, over input bandwidth, measured at VREF+ - VREF-.
- e. Internal reference is connected directly between  $V_{DDA}$  and GNDA ( $VREFi = V_{DDA} - GNDA$ ). In this mode,  $E_O$ ,  $E_G$ ,  $E_T$ , and dynamic specifications are adversely affected due to internal voltage drop and noise on  $V_{DDA}$  and GNDA. Internal reference voltage is selected when VREF field in the **ADCTL** register is 0x0.
- f.  $V_{ADCIN} = V_{INP} - V_{INN}$
- g. With signal common mode as  $V_{DDA}/2$ .
- h. With signal common mode as  $(V_{REF+} + V_{REF-})/2$ .
- i. This parameter is defined as the average of the differential inputs.
- j. As shown in Figure 30-29 on page 1941,  $R_{ADC}$  is the total equivalent resistance in the input line all the way up to the sampling node at the input of the ADC.
- k. See "System Clock Specification with ADC Operation" on page 1921 for full ADC clock frequency specification.
- l. ADC conversion time ( $T_c$ ) includes the ADC sample time ( $T_s$ ).
- m. Low noise environment is assumed in order to obtain values close to spec. Board must have good ground isolation between analog and digital grounds, a clean reference voltage is assumed, and input signal must be bandlimited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- n. ADC static measurements taken by averaging over several samples. At least 20-sample averaging is assumed to obtain expected typical or maximum spec values.
- o. 12-bit DNL
- p. Gain error is measured at max code after compensating for offset. Gain error is equivalent to "Full Scale Error." It can be given in % of slope error, or in LSB, as done here.
- q. Total Unadjusted Error is the maximum error at any one code versus the ideal ADC curve. It includes all other errors (offset error, gain error and INL) at any given ADC code.
- r. A low noise environment is assumed in order to obtain values close to spec. The board must have good ground isolation between analog and digital grounds and a clean reference voltage. The input signal must be band-limited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- s. ADC dynamic characteristics are measured using low-noise board design, with low-noise reference voltage ( $< -74$ dB noise level in signal BW) and low-noise analog supply voltage. Board noise and ground bouncing couple into the ADC and affect dynamic characteristics. Clean external reference must be used to achieve shown specs.
- t. Differential signal with correct common mode, applied between two ADC inputs.
- u.  $SDR = -THD$  in dB.
- v. For higher frequency inputs, degradation in SDR should be expected.
- w.  $SNDR = S/(N+D) = SINAD$  (in dB)
- x. Effective number of bits (ENOB) can be calculated from SNDR:  $ENOB = (SNDR - 1.76) / 6.02$ .
- y. Single ended inputs are more sensitive to board and trace noise than differential inputs; SNR and SNDR measurements on single-ended inputs are highly dependent on how clean the test set-up is. If the input signal is not well-isolated on the board, higher noise than specified could potentially be seen at the ADC output.
- z. Note that this parameter does not include ADC error.

| S13           | $T_{RXDSSU}$    | Slave Mode: Rx Data In (from master) setup time                                 | 0                  | -   | -                  | ns   |
| S14           | $T_{RXDSH}$     | Slave Mode: Rx Data In (from master) hold time                                  | 37.03 <sup>f</sup> | -   | -                  | ns   |

a. In master mode, the system clock must be at least twice as fast as the SSIClk.

b. In slave mode, the system clock must be at least 12 times faster than the SSIClk.

c. Note that the delays shown are using 12-mA drive strength.

d. This MAX value is for the minimum slave mode  $T_{SYSCLK}$  period (8.33 ns). To find the MAX  $T_{TXDSOV}$  value for a larger  $T_{SYSCLK}$ , use the equation:  $4 * T_{SYSCLK} + 14.25$ .

e. This MIN value is for the minimum slave mode  $T_{SYSCLK}$  (8.33 ns). To find the MIN  $T_{TXDSOH}$  value for a larger  $T_{SYSCLK}$ , use the equation:  $4 * T_{SYSCLK} + 4.08$ .

f. This MIN value is for the minimum slave mode  $T_{SYSCLK}$  (8.33 ns). To find the MIN  $T_{TXDSH}$  value for a larger  $T_{SYSCLK}$ , use the equation:  $4 * T_{SYSCLK} + 3.70$ .

| I5 <sup>c</sup> | $T_{SFT}$  | I2CSCL/I2CSDA fall time ( $V_{IH}=2.4\text{ V}$ to $V_{IL}=0.5\text{ V}$ ) | -   | 9                     | 10           | ns            |
| I6 <sup>a</sup> | $T_{HT}$   | Clock High time                                                            | 24  | -                     | -            | system clocks |
| I7              | $T_{DS}$   | Data setup time                                                            | 18  | -                     | -            | system clocks |
| I8 <sup>a</sup> | $T_{SCSR}$ | Start condition setup time (for repeated start condition only)             | 36  | -                     | -            | system clocks |
| I9 <sup>a</sup> | $T_{SCS}$  | Stop condition setup time                                                  | 24  | -                     | -            | system clocks |
| I10             | $T_{DV}$   | Data Valid (slave)                                                         | -   | 2                     | -            | system clocks |
|                 |            | Data Valid (master)                                                        | -   | $(6 * (1 + TPR)) + 1$ | -            | system clocks |

a. Values depend on the value programmed into the TPR bit in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register; a TPR programmed for the maximum I2CSCL frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I<sup>2</sup>C interface is designed to scale the actual data transition time to move it to the middle of the I2CSCL Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.

b. Because I2CSCL and I2CSDA operate as open-drain-type signals, which the controller can only actively drive low, the time I2CSCL or I2CSDA takes to reach a high level depends on external signal capacitance and pull-up resistor values.

c. Specified at a nominal 50 pF load.

## 30.20 Universal Serial Bus (USB) Controller

The Tiva™ C Series USB controller electrical specifications are compliant with the *Universal Serial Bus Specification Rev. 2.0* (full-speed and low-speed support) and the *On-The-Go Supplement to the USB 2.0 Specification Rev. 1.0*. Some components of the USB system are integrated within the TM4C129DNCZAD microcontroller and specific to the Tiva™ C Series microcontroller design.

**Note:** GPIO pin, PB1, which can be configured as the USB0VBUS signal, is the only pin which is 5-V tolerant on the device.

Table 30-59. ULPI Interface Timing

| Parameter No.                                                  | Parameter | Parameter Name                           | Min | Nom | Max  | Unit |

## 30.21 Analog Comparator

Table 30-60. Analog Comparator Characteristics<sup>ab</sup>

| Parameter            | Parameter Name                  | Min  | Nom | Max       | Unit |
|----------------------|---------------------------------|------|-----|-----------|------|
| $V_{INP}, V_{INN}^c$ | Input voltage range             | GNDA | -   | $V_{DDA}$ | V    |
| $V_{CM}$             | Input common mode voltage range | GNDA | -   | $V_{DDA}$ | V    |

**Table 30-60. Analog Comparator Characteristics (continued)**

| Parameter                           | Parameter Name                                | Min | Nom | Max              | Unit |
|-------------------------------------|-----------------------------------------------|-----|-----|------------------|------|
| V <sub>OS</sub>                     | Input offset voltage                          | -   | ±10 | ±50 <sup>d</sup> | mV   |
| I <sub>INP</sub> , I <sub>INN</sub> | Input leakage current over full voltage range | -   | -   | 2.0              | µA   |
| C <sub>MRR</sub>                    | Common mode rejection ratio                   | -   | 50  | -                | dB   |
| T <sub>RT</sub>                     | Response time                                 | -   | -   | 1.0 <sup>e</sup> | µs   |
| T <sub>MC</sub>                     | Comparator mode change to Output Valid        | -   | -   | 10               | µs   |

a. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk.

b. To achieve best analog results, the source resistance driving the analog inputs, V<sub>INP</sub> and V<sub>INN</sub>, should be kept low.

c. The external voltage inputs to the Analog Comparator are designed to be highly sensitive and can be affected by external noise on the board. For this reason, V<sub>INP</sub> and V<sub>INN</sub> must be set to different voltage levels during idle states to ensure the analog comparator triggers are not enabled. If an internal voltage reference is used, it should be set to a mid-supply level. When operating in Sleep/Deep-Sleep modes, the Analog Comparator module should be disabled or the external voltage inputs set to different levels (greater than the input offset voltage) to achieve minimum current draw.

d. Measured at VREF=100 mV.

e. Measured at external VREF=100 mV, input signal switching from 75 mV to 125 mV.

**Table 30-61. Analog Comparator Voltage Reference Characteristics**

| Parameter       | Parameter Name               | Min | Nom                     | Max                 | Unit |
|-----------------|------------------------------|-----|-------------------------|---------------------|------|
| R <sub>HR</sub> | Resolution in high range     | -   | V <sub>DDA</sub> /29.4  | -                   | V    |
| R <sub>LR</sub> | Resolution in low range      | -   | V <sub>DDA</sub> /22.12 | -                   | V    |
| A <sub>HR</sub> | Absolute accuracy high range | -   | -                       | ±R <sub>HR</sub> /2 | V    |
| A <sub>LR</sub> | Absolute accuracy low range  | -   | -                       | ±R <sub>LR</sub> /2 | V    |

# A Package Information

## A.1 Orderable Devices

Figure A-1. Key to Part Numbers

Table A-1. Orderable Part Numbers

| Part Number     | Description                                                                                    |
|-----------------|------------------------------------------------------------------------------------------------|
| TM4C129DNCZADI  | Tiva™ C Series TM4C129DNCZAD Microcontroller Industrial Temperature 212-ball BGA               |
| TM4C129DNCZADIR | Tiva™ C Series TM4C129DNCZAD Microcontroller Industrial Temperature 212-ball BGA Tape-and-reel |
| TM4C129DNCZADT  | Tiva™ C Series TM4C129DNCZAD Microcontroller Extended Temperature 212-ball BGA                 |
| TM4C129DNCZADTR | Tiva™ C Series TM4C129DNCZAD Microcontroller Extended Temperature 212-ball BGA Tape-and-reel   |

## A.2 Part Markings

Tiva™ C Series microcontrollers are marked with an identifying number, as shown in the figure below.

This identifying number contains the following information:

- **Lines 1 and 5:** Internal tracking numbers

- **Lines 2 and 3:** Part number

For example, TM4C123G on the second line followed by E6PZI on the third line indicates orderable part number TM4C123GE6PZI. The first letter in the part number indicates the product status. A T indicates the part is fully qualified and released to production; an X indicates the part is experimental (pre-production) and requires a waiver. Pre-production parts also include a revision number in the part number, for example, XM4C123G followed by E6PZI5 indicates revision 5. Production parts do not include a revision number in the part number. Some devices also include an internal code after the temperature character field. The **DID0** register identifies the version of the microcontroller. The MAJOR and MINOR bit fields indicate the die revision number. Combined, the MAJOR and MINOR bit fields indicate the TM4C129x microcontroller part revision number.

| MAJOR Bitfield Value | MINOR Bitfield Value | Die Revision | Part Revision |
|----------------------|----------------------|--------------|---------------|
| 0x0                  | 0x0                  | A0           | 1             |
| 0x0                  | 0x1                  | A1           | 2             |

- **Line 4:** Date code

The first two characters on the fourth line indicate the date code, followed by internal tracking numbers. The two-digit date code YM indicates the last digit of the year, then the month. For example, a 34 for the first two digits of the fourth line indicates a date code of April 2013.

## A.3 Packaging Diagram

Figure A-2. TM4C129DNCZAD 212-Ball BGA Package Diagram

### MECHANICAL DATA

ZAD (S-PBGA-N212)

PLASTIC BALL GRID ARRAY

- NOTES:
- A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
  - B. This drawing is subject to change without notice.
  - C. This is a Pb-free solder ball design.

## PACKAGING INFORMATION

| Orderable Device | Status<br>(1) | Package Type | Package<br>Drawing | Pins | Package<br>Qty | Eco Plan<br>(2) | Lead/Ball Finish<br>(6) | MSL Peak Temp<br>(3) | Op Temp (°C) | Device Marking<br>(4/5) | Samples |
|------------------|---------------|--------------|--------------------|------|----------------|-----------------|-------------------------|----------------------|--------------|-------------------------|---------|
| XM4C129DNCZADI1  | PREVIEW       | NFBGA        | ZAD                | 212  | 1              | TBD             | Call TI                 | Call TI              | -40 to 85    |                         |         |

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
