**Register 45: EPI Host-Bus 16 Timing Extension (EPIHB16TIME4), offset 0x31C**

**Important:** The MODE field in the **EPICFG** register determines which configuration is enabled.

For **EPIHB16TIME4** to be valid, the MODE field must be 0x3.

## EPI Host-Bus 16 Timing Extension (EPIHB16TIME4)

Base 0x400D.0000

Offset 0x31C

Type RW, reset 0x0002.2000

**Register 46: EPI Host-Bus PSRAM (EPIHBPSRAM), offset 0x360**

This register holds the PSRAM configuration register value. When the WRCRE bit in the **EPIHB16CFGn** register is set, all 21 bits of the **EPIHBPSRAM** register's CR value are written to the PSRAM's configuration register. When the RDCRE bit is set in the **EPIHB16CFGn** register, a read of the PSRAM's configuration register takes place and the value is written to bits[15:0] of the **EPIHBPSRAM**. Bits[20:16] will not contain any valid data.

**EPI Host-Bus PSRAM (EPIHBPSRAM)**

Base 0x400D.0000

Offset 0x360

Type RW, reset 0x0000.0000

## 12 Cyclical Redundancy Check (CRC)

The Cyclical Redundancy Check (CRC) computation module can be used for message transfer and safety system checks, as well as in conjunction with the AES and DES modules. The following features are supported:

- Support four major CRC forms:
  - CRC16-CCITT as used by CCITT/ITU X.25
  - CRC16-IBM as used by USB and ANSI
  - CRC32-IEEE as used by IEEE802.3 and MPEG2
  - CRC32C as used by G.Hn
- Allows word and byte feed
- Supports auto-initialization and manual initialization
- Supports MSb and LSb
- Supports CCITT post-processing
- Can be fed by  $\mu$ DMA, Flash memory and code

### 12.1 Functional Description

The following sections describe the features of CRC.

#### 12.1.1 CRC Support

The purpose of the CRC engine is to accelerate CRC and TCP checksum operation. The result of the CRC operation is a 32- and 16-bit signature which can be used to check the sanity of data. The required mode of operation is selected through the TYPE bit in the **CRC Control (CRCCTRL)** register, offset 0x400. A  $\mu$ DMA software channel can be used to burst data into the CRC module. CRCs are computed combinatorially in one clock.

The CRC module contains all of the control registers to which the input context interfaces. Because CRC calculations are a single cycle, as soon as data is written to **CRC Data Input (CRCDIN)** register, the result of CRC/CSUM is updated in the **CRC SEED/Context (CRCSEED)** register, offset 0x410. The input data is computed by the selected CRC polynomial or CSUM.

##### 12.1.1.1 CRC Checksum engine

Software can offload the CRC and checksum task to the CRC checksum engine accelerator. The accelerator has registers that need to be programmed to initiate processing. These registers should be fed with data in order to calculate CRC/CSUM. Software should configure the  $\mu$ DMA channel for data movement through the **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA module. Further  $\mu$ DMA configuration guidelines are available in the “Micro Direct Memory Access ( $\mu$ DMA)” on page 677.

The starting seed for the CRC and checksum operation is programmed in the **CRC SEED/Context (CRCSEED)** register at offset 0x410. Depending on the encoding of the INIT field in the **CRCCTRL** register, the value of the SEED field can be initialized to any one of the following:

- A unique context value written to the **CRCSEED** register (INIT=0x0)
- All 0s (INIT=0x2)
- All 1s (INIT=0x3)

Once the operation is done, software should read the result from the **CRC Post Processing Result (CRCRSLTPP)** register, offset 0x418, and a software channel  $\mu$ DMA interrupt should be used to identify completion.

### 12.1.1.2 Data Size

The CRC module supports data being fed 32-bit words and 8 bits at a time and can dynamically switch back and forth. The data size is configured by programming the SIZE bit in the **CRCCTRL** register, offset 0x400.

Because CRC is a division on a long stream of bits, the application must take into consideration the bit order. When processing message data that is read out by words, bit order is not an issue. For example, if the data value in the message is 0x12345678, the most significant eight byte is 0x12 (00010010 in binary). If the data is processed as bytes, 0x12, 0x34, 0x56, and 0x78 are copied into memory in that order and the word is stored as 0x78563412, where 0x12 is written as byte 0, 0x34 is written as byte 1, and so on.

### 12.1.1.3 Endian Configuration

The following endian configuration is provided by the ENDIAN field in the **CRCCTRL** register:

- Swap byte in half-word
- Swap half word

Input data width is four bytes, hence the configuration only affects the four-byte word. The ENDIAN bit field supports the following configurations, assuming the input word is {B3, B2, B1, B0}

**Table 12-1. Endian Configuration**

| ENDIAN Encoding | Definition                                                     | Configuration    |
|-----------------|----------------------------------------------------------------|------------------|
| 0x0             | Configuration unchanged.                                       | {B3, B2, B1, B0} |
| 0x1             | Bytes are swapped in half-words but half-words are not swapped | {B2, B3, B0, B1} |
| 0x2             | Half-words are swapped but bytes are not swapped in half-word. | {B1, B0, B3, B2} |
| 0x3             | Bytes are swapped in half-words and half-words are swapped.    | {B0, B1, B2, B3} |

Bit reversal is supported by the BR bit in the **CRCCTRL** register. The bit reversal operation works in tandem with endian control. For example, the above table with the BR option set would look like this:

**Table 12-2. Endian Configuration with Bit Reversal**

| ENDIAN Encoding | Initial Endian Configuration                                          | Configuration with Bit Reversal (BR = 1) |
|-----------------|-----------------------------------------------------------------------|------------------------------------------|
| 0x0             | Configuration unchanged.<br>{B3[31:24], B2[23:16], B1[15:8], B0[7:0]} | B3[24:31], B2[16:23], B1[8:15], B0[0:7]  |

**Table 12-2. Endian Configuration with Bit Reversal (continued)**

| ENDIAN Encoding | Initial Endian Configuration                                                                                | Configuration with Bit Reversal (BR = 1) |
|-----------------|-------------------------------------------------------------------------------------------------------------|------------------------------------------|
| 0x1             | Bytes are swapped in half-words but half-words are not swapped<br>{B2[23:16], B3[31:24], B0[7:0], B1[15:8]} | B2[16:23],B3[24:31],B0[0:7],B1[8:15]     |
| 0x2             | Half-words are swapped but bytes are not swapped in half-word.<br>{B1[15:8], B0[7:0], B3[31:24], B2[23:16]} | B1[8:15],B0[0:7],B3[24:31],B2[16:23]     |
| 0x3             | Bytes are swapped in half-words and half-words are swapped<br>{B0[7:0], B1[15:8], B2[23:16], B3[31:24]}     | B0[0:7],B1[8:15],B2[16:23],B3[24:31]     |

## 12.2 Initialization and Configuration

The following describes the initialization and configuration procedures of the CRC module.

### 12.2.1 CRC Initialization and Configuration

The CRC engine works in push through mode, which means it works on streaming data. This section describes the steps for initializing the CRC module:

1. Enable the CRC by setting the R0 bit in the CRC and Cryptographic Modules (RCGCCM) register, System Control offset 0x674.
2. Configure the desired CRC data size, bit order, endian configuration and CRC type by programming the **CRC Control (CRCCTRL)** register, offset 0x400.
3. If the CRC value has not been initialized to all 0s or all 1s using the INIT field in the **CRCCTRL** register, program the initial value in the **CRC SEED/Context (CRCSEED)** register, offset 0x410.
4. Repeatedly write the DATAIN field in the **CRC Data Input (CRCDIN)** register, offset 0x414. If the SIZE bit in the **CRCCTRL** register is set to select byte, the CRC engine operates in byte mode and only the least significant byte is used for CRC calculation.
5. When CRC is finished, read the **CRCSEED** register for the final result. If using post-processing, the raw CRC result is stored in the **CRCSEED** register and the final, post-processed result can be read from the **CRC Post-Processing Result (CRCRSLTPP)** register, offset 0x418.  
Post-processing options are selectable through the OBR and OLVN bits of the **CRCCTRL** register.

Alternatively a software  $\mu$ DMA channel can be configured to copy data from the source into the **CRCDIN** register. When configuring the  $\mu$ DMA, the destination should be configured to not increment. For more information on how to configure the  $\mu$ DMA, refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 677.

#### 12.2.1.1 Data Endian Convention for the CRC Engine

If the input stream is expressed as a byte stream, Din, where Din = {D0, D1, D2, D3, D4, D5, D6, D7, D8, D9, D11, D12, D13, D14, D15, D16.....}, then data should be fed to the CRC engine as follows:

- If operating in Byte mode, the **CRCDIN** register should be written in the following order:
  1. {00, 00, 00, D0}

2. {00, 00, 00, D1}

3. {00, 00, 00, D2}

4. {00, 00, 00, D3}

5. {00, 00, 00, D4}

6. {00, 00, 00, D5}

7. {00, 00, 00, D6}

8. ....

9. ....

- If operating in word mode, the **CRC DIN** register should be written in the following order:

1. {D3, D2, D1, D0}

2. {D7, D6, D5, D4}

3. {D11, D10, D9, D8}

4. ....

5. ....

## 12.3 Register Map

Table 12-3 on page 950 lists the CRC Module registers. The offset listed is a hexadecimal increment to the register's address, relative to the base address 0x4403.0000.

**Table 12-3. CCM Register Map**

| Offset | Name      | Type | Reset       | Description                | See page |
|--------|-----------|------|-------------|----------------------------|----------|
| 0x400  | CRCCTRL   | RW   | 0x0000.0000 | CRC Control                | 951      |
| 0x410  | CRCSEED   | RW   | 0x0000.0000 | CRC SEED/Context           | 953      |
| 0x414  | CRC DIN   | RW   | 0x0000.0000 | CRC Data Input             | 954      |
| 0x418  | CRCRSLTPP | RO   | 0x0000.0000 | CRC Post Processing Result | 955      |

## 12.4 CRC Module Register Descriptions

This section lists and describes the CRC registers, in numerical order by address offset.

**Note:** The CRC module can only be accessed through privileged mode. If the  $\mu$ DMA is used for CRC transfers, then the  $\mu$ DMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

## Register 1: CRC Control (CRCCTRL), offset 0x400

The **CRC Control (CRCCTRL)** register is used to configure control of the CRC.

### CRC Control (CRCCTRL)

Base 0x4403.0000

**Register 2: CRC SEED/Context (CRCSEED), offset 0x410**

The **CRC SEED/Context (CRCSEED)** register is initially written with one of the following three values depending on the encoding of the INIT field in the **CRCCTRL** register:

- The context value written to the **CRCSEED** register. This encoding is for SEED values from a previous CRC calculation or a specific protocol. (INIT=0x0)
- 0x0000.0000 (INIT=0x2)
- 0x1111.1111 (INIT=0x3)

**CRC SEED/Context (CRCSEED)**

Base 0x4403.0000

Offset 0x410

Type RW, reset 0x0000.0000

## 13 Advance Encryption Standard Accelerator (AES)

This section describes the Advanced Encryption Standard (AES) cryptographic hardware-accelerated module.

### 13.1 AES Overview

This section introduces the AES and describes the AES main functions and connections in the device.

The advanced encryption standard (AES) security modules provide hardware-accelerated data encryption and decryption operations based on a binary key. The AES is a symmetric cipher module that supports a 128-bit, 192-bit, or 256-bit key in hardware for both encryption and decryption. The AES module is based on a symmetric algorithm, meaning that the encryption and decryption keys are identical. To encrypt data means to convert it from plain text to an unintelligible form called cipher text. Decrypting cipher text converts previously encrypted data back to its original plain text form.

The main features of the AES accelerator are:

- Support for basic AES encrypt and decrypt operations:
  - Galois/Counter Mode (GCM), with basic GHASH operation
  - Counter Mode with CBC-MAC (CCM)
  - XTS Mode
- Availability of the following feedback operating modes:
  - Electronic Code Book Mode (ECB)
  - Cipher Block Chaining Mode (CBC)
  - Counter Mode (CTR)
  - Cipher Feedback Mode (CFB), 128-bit
  - F8 Mode
- Key sizes 128-, 192- and 256-bits
- Support for CBC\_MAC and Fedora 9 (F9) authentication modes
- Basic GHASH operation (when selecting no encryption)
- Key scheduling in hardware
- Support for  $\mu$ DMA transfers
- Fully synchronous design

### 13.2 AES Functional Description

The following sections describe the features of the AES Module.

### 13.2.1 AES Block Diagram

Figure 13-1 on page 957 shows the AES block diagram. A single-core/dual-interface architecture is used.

**Figure 13-1. AES Block Diagram**

AES is an efficient implementation of the Rijndael cipher (the AES algorithm) and a 128-bit polynomial multiplication (referred to here as GHASH, as per the AES-GCM specification). Rijndael is a block cipher in which each data block is 128 bits. The polynomial multiplication multiplies two 128-bit vectors using the smallest 128-bit irreducible polynomial, represented by the following 128-bit string:  $\{0^{120}\}||10000111$ . The two implementations are combined into the AES wide-bus engine.

Depending on the availability of context and data, the AES wide-bus engine is automatically triggered to process the data. The AES wide-bus engine is directly connected to the context and data registers so that it can immediately start processing when all data is available. The AES wide-bus engine also interfaces to the I/O Control FSM/μDMA Request Interface.

AES comprises the following major functional blocks:

- Global control FSM and μDMA interface
- Register interface module
- The AES wide-bus engine

The AES wide-bus engine, which is the major top-level component, comprises the following functional blocks:

- Mode control FSM: Manages the data flow to and from the AES wide-bus engine and starts each encryption/decryption operation.

- Feedback modes: The logic that implements the various feedback modes supported by AES.
- GHASH core: The polynomial multiplication algorithm used for AES-GCM
- AES key scheduler: Generates AES encryption and decryption (round) keys
- AES encryption core: The AES encryption algorithm
- AES decryption core: The AES decryption algorithm
- Substitution-boxes (S-Boxes): Contain AES S-Box GF(2<sup>8</sup>) implementations

AES encryption requires a specific number of rounds, depending on the key length. The supported key lengths are 128-, 192-, and 256-bit, which require 10, 12, and 14 rounds, respectively, or 32, 38, and 44 clock cycles, respectively, because {number of clock cycles} = 2 + 3 x {number of rounds}.

The larger key lengths provide greater encryption strength at the expense of additional rounds and therefore reduced throughput. The overall throughput of the AES executing polynomial multiplication is adjusted based on the overall cryptographic performance. The AES module contains one Electronic Codebook (ECB) core and a dedicated 32-cycle polynomial multiplication module for performing GHASH operations. Polynomial multiplication operates in parallel with the AES core, if data is available for both modules.

Depending on the key size (128/192/256 bits), this core requires 32, 38, or 44 clock cycles to process one 128-bit data block. While one data block processes, the next block can be preloaded immediately. When a block is preloaded, the previous block must finish before additional data can be loaded. Therefore, once the pipeline is full, sequential data blocks can be passed every 32, 38, or 44 clock cycles.

### 13.2.1.1 Interfaces

The interface signals to the AES module can be grouped into the following four categories:

- Clock and reset signals
- Register interface
- $\mu$ DMA/INT interface, used to request new context and packet data or to indicate available result data (encrypted/decrypted data or authentication result)

### 13.2.1.2 Register Interface

The register interface block performs all address decoding and control. However, not all registers are located in this block. The context and data input registers are in the AES wide-bus engine. The data output registers are available in this block.

### 13.2.1.3 AES Wide-Bus Engine

The AES wide-bus engine performs the cryptographic operations. The composition of the AES core is:

- The main data path operates on the input block, performing the required substitution, shift, and mix operations.
- The key scheduler generates the round keys. A new subkey is generated and XORed with the data each round.

**AES Key Scheduler**

The AES key scheduler generates the round keys. During each round, a new subkey is generated from the input key to be XORed with the data. Round keys are generated on-the-fly and parallel to data processing to minimize register requirements.

For encryption operations, the key sequencer transfers the initial key data to the AES core. For decryption operations, the key scheduler must provide the final subkey to the AES core so it can generate the subkeys in reverse order.

**AES Encryption Core**

The AES encryption core implements the Rijndael algorithm as specified in [ FIPS-197]. This core operates on the input block and performs the required substitution, shift, and mix operations. For each round, the encryption core receives the proper round key from the AES key scheduler. A fundamental component of the AES algorithm is the S-Box. The S-Box provides a unique 8-bit output for each 8-bit input. This implementation of the AES encryption core has a 64-bit data path.

**AES Decryption Core**

The architecture of the AES decryption core is generally the same as the architecture of the encryption core. One difference is that the generation of round keys for decryption requires an initial conversion of the input key (always supplied by the host in the form of an encryption key) to the corresponding decryption key. This conversion is done by performing a dummy encryption operation and storing the final round key as a decryption key. The key scheduler is then reversed to generate the round keys for the decryption operation. Consequently, for each sequence of decryption operations under the same key, a single throughput reduction equal to the time to encrypt a single block occurs. Once a decryption key is generated, subsequent decryption operations with the same key use this generated decryption key directly.

**AES Feedback Mode Block**

The AES feedback mode block buffers the feedback parameters and controls the various feedback modes. For more information about the ECB, CBC, CTR, and CFB modes of operation, see the [NIST-SP800-38A](#) specification.

CTR implements the standard incrementing function, as described in the NIST-SP800-38A specification, with  $m$  set to 16 or a multiple of 32.

AES-XTS mode requires a polynomial multiplication for initialization vector (IV) generation of the AES operation. This multiplication can be simplified when the first result is available due to the definition and use of the block number within a unit. The input for the polynomial multiplication is not directly  $j$ , but  $\alpha^j$ , where  $\alpha = x^2$  in the  $GF(2^{128})$  domain.

In addition, f8 encryption/decryption mode and f9 and (X)CBC-MAC authentication modes are available.

**GHASH Block**

The data sequencer manages the data flow to and from the AES core. For data input, the data sequencer monitors the input buffer until a 16-byte block is available. If the AES core is idle, the data sequencer writes this data block to the internal working registers of the AES core, thus clearing the buffer for the next block.

After completing an encryption or decryption operation, the data sequencer writes the AES output to the output buffer. If the output buffer is full at the time of completion, the AES core is held until the buffer clears. Although the data sequencer is designed to support uninterrupted packet encryption, the host must properly manage the input and output packet buffers to achieve optimal performance.

### 13.2.2 AES Algorithm

The AES algorithm generates block ciphers. The AES block size is 16 bytes. The AES key(s) can be coded on 128, 192, or 256 bits. The larger key sizes provide a higher level of security, but at the cost of a moderate decrease in throughput.

For the AES algorithm:

- The length of the input and output blocks is 128 bits, which is represented by  $N_b = 4$ , which reflects the number of 32-bit words.
- The length of the cipher key (K) is 128, 192, or 256 bits. The key length is represented by  $N_k = 4, 6, \text{ or } 8$ , which reflects the number of 32-bit words in the cipher key.
- The number of rounds to be performed during the execution of the algorithm is dependent on the key size. The number of rounds is represented by  $N_r$ , where  $N_r = 10$  when  $N_k = 4$  (128-bit key);  $N_r = 12$  when  $N_k = 6$  (192-bit key); and  $N_r = 14$  when  $N_k = 8$  (256-bit key).

Table 13-1 on page 960 lists the combinations of keys, blocks, and rounds.

**Table 13-1. Key-Block-Round Combinations**

| Key      | Key Length ( $N_k$ ) | Block Size ( $N_b$ ) | Number of Rounds ( $N_r$ ) |
|----------|----------------------|----------------------|----------------------------|
| 128 bits | 4                    | 4                    | 10                         |
| 192 bits | 6                    | 4                    | 12                         |
| 256 bits | 8                    | 4                    | 14                         |

The AES algorithm for cipher and inverse cipher uses a round function composed of four different byte-oriented transformations:

- Byte substitution using a substitution table (S-Box)

This transformation is a non-linear byte substitution that operates independently on each byte of the state (the state is an intermediate processed block of 128 bits inside the AES; the state is arranged as an array of  $[4 \times N_k]$  bytes) using an S-Box. This S-Box transformation is reversible.

- Shifting rows of the state array by different offsets

In this transformation, the bytes in the last three rows of the state are cyclically shifted over different numbers of bytes (offsets). The first row ( $r = 0$ ) is not shifted.

- Mixing the data within each column of the state array

This transformation operates on the state column-by-column, treating each column as a four-term polynomial. The columns are considered polynomials over  $GF(2^8)$  and multiplied modulo  $x^4 + 1$  with a fixed polynomial  $a(x)$ .

- Adding a round key to the state

In this transformation, a round key is added to the state by a simple bitwise XOR operation. Each round key consists of  $N_b$  words from the key schedule.

The AES algorithm takes the cipher key (K) and performs a key expansion routine to generate a key schedule. The key expansion generates a total of  $N_b \times (N_r + 1)$  words: The algorithm requires an initial set of  $N_b$  words, and each of the  $N_r$  rounds requires  $N_b$  words of key data. The resulting key schedule consists of a linear array of 4-byte words, denoted  $[w_i]$ , with  $i$  in the range  $0 \leq i < N_b \times (N_r + 1)$ .

### 13.2.3 AES Operating Modes

#### 13.2.3.1 Supported Modes of Operation

##### **ECB Feedback Mode**

Figure 13-2 on page 961 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output is passed directly to the output buffer.

For decryption, the cryptographic core operates in reverse: the decryption data path is used for data processing, whereas encryption uses the encryption data path.

**Figure 13-2. AES - ECB Feedback Mode**

##### **CBC Feedback Mode**

Figure 13-3 on page 962 shows the CBC feedback mode of operation, where the input data is XORed with the IV before it is passed to the basic cryptographic core. The output of the cryptographic core passes directly to the output buffer and becomes the next IV.

The operation is reversed for decryption, resulting in an XOR at the output of the cryptographic core. The input cipher text of the current operation is the IV for the next operation.

Figure 13-3. AES - CBC Feedback Mode

**CTR and ICM Feedback Modes**

Figure 13-4 on page 962 shows the counter feedback (CTR/ICM) mode of operation. This operation encrypts the IV. The output of the cryptographic core (encrypted IV) is XORed with the data, thus creating the output result.

The IV is built out of two components: a fixed part and a counter part. The counter part is incremented with each block. The counter width is selectable per context and can be 16, 32, 64, 96, or 128 bits wide. In this mode, encryption and decryption use the same operation.

Figure 13-4. AES Encryption With CTR/ICM Mode

**Note:** The value for n can be 1, 2, 3, or 4 for CTR mode and is ½ for ICM mode.

### CFB Mode

Figure 13-5 on page 963 shows the full block (128 bits) CFB mode of operation for encryption and decryption. The input for the cryptographic core is the IV; the result is XORed with the data. The result is fed back through the IV register as the next input for the cryptographic core. The decryption operation is reversed, but the cryptographic core still performs encryption.

**Figure 13-5. AES - CFB Feedback Mode**

### F8 Mode

Figure 13-6 on page 964 shows the F8 feedback mode of operation for encryption and decryption. The input to the cryptographic core is the result of the XOR operation of the previous cryptographic core output, a constant IV, and a block counter. The output of the cryptographic core is XORed with the input to create the result. In this mode, encryption and decryption use the same operations.

**Figure 13-6. AES - F8 Mode****XTS Operation**

Figure 13-7 on page 964 shows the XTS mode of operation for encryption and decryption. The input to the cryptographic core is XORed with the IV; the output of the cryptographic core is XORed with the same IV. For decryption, the cryptographic core operates in reverse, but the XOR operations are the same.

**Figure 13-7. AES - XTS Operation**

**Note:** The IV is created with an initial encryption, followed by an LFSR operation for each new block.

### F9 Operation

Figure 13-8 on page 965 shows the F9 authentication mode of operation, where the input to the cryptographic core is XORed with the IV, and the output is XORed with the previous result to create the next result. The cryptographic core output is fed back as IV for the next block. The result is the output of the last XOR operation of the cryptographic core output.

**Figure 13-8. AES - F9 Operation**

### CBC-MAC Operation

Figure 13-9 on page 966 shows the CBC-MAC authentication mode of operation, where the input to the cryptographic core is XORed with the IV. The cryptographic core output is then fed back as IV for the next block. The last data input block is XORed with an additional input value stored in the temporary buffer; this can be any precalculated value and is dependent on the alignment of the last input block. The result is the cryptographic core output of the last encryption operation.

**Figure 13-9. AES - CBC-MAC Authentication Mode****GCM Operation**

Figure 13-10 on page 967 shows one round of a GCM operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. After the encryption/decryption, the ciphertext is XORed with the intermediate authentication result. The XORed result is used as input for the polynomial multiplication to create the next (intermediate) authentication result. For more information about the GCM protocol, see the section called "GCM Protocol Operation" on page 968.

**Figure 13-10. AES - GCM Operation****CCM Operation**

Figure 13-11 on page 968 shows one round of a CCM (counter with CBC-MAC) operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. Immediately after the encryption operation, the plaintext is XORed with the intermediate authentication result. The XOR result is used as input for a second encryption operation to calculate the next (intermediate) authentication result.

Figure 13-11. AES - CCM Operation

### 13.2.3.2 Extended and Combined Modes of Operations

This section describes the protocols (or autonomous precalculations) supported by the AES wide-bus engine.

#### GCM Protocol Operation

A GCM protocol operation is a combined operation consisting of encryption/decryption and authentication. A part of the input data stream can be authenticated only, while normally most of the input data is encrypted/decrypted and authenticated. The authentication-only data must always be in front of the data requiring encryption. Within GCM, the authentication-only data is called the additional authentication data (AAD). The AAD is fetched independently of other data.

The intermediate (temporary) result data is used as input to the remaining authentication operation. Because the authentication operation does not require the cryptographic core but only the polynomial multiplication, encryption/decryption and authentication can be performed in parallel. After encryption of the last data block, additional polynomial multiplication and encryption are required to authenticate a 128-bit length vector and finally encrypt the authentication result.

#### CCM Protocol Operation

The CCM protocol operation is a combined operation consisting of encryption/decryption and authentication. The authentication and encryption/decryption operations use the cryptographic core; these are executed sequentially on the AES core. A part of the data stream can require authentication only. The authentication-only data must always be in front of the data requiring encryption.

Authentication starts with the encryption of a predefined block B0. This block consists of flags, nonce, and message length. The next blocks contain the authentication data length concatenated with the authentication-only data. After processing the authentication-only data, the encryption/decryption operations are performed, each followed by the related authentication of the plaintext data block (which equals the input in the case of encryption, and the output in the case of

decryption). The final authentication result must be encrypted using the output of the encryption of the IV block A0. This block contains the IV (consisting of flags and nonce) concatenated with the counter, which is zero for A0.

### 13.2.4 AES Software Reset

To perform a software reset of the AES module, write a 1 to the SOFTRESET bit in the **AES System Configuration (AES\_SYSCONFIG)** register. The RESETDONE bit in the **AES Secure System Status (AES\_SYSTATUS)** register indicates that the software reset is complete when its value is 1. When the software reset completes, the SOFTRESET bit in the **AES\_SYSCONFIG** register is automatically reset. Software must ensure that the software reset completes before doing any operations.

The behavior of the software reset is the same as the hardware reset, except that the software reset bit resets this module without affecting the reset core domain of the entire device.

### 13.2.5 Power Management

To save power, the application can disable the clock to the AES module when not in use. The AES is clock gated by setting the AESCFG bit in the **Cryptographic Modules Clock Gating Request (CCMCGREQ)** register, CRC and Cryptographic Modules (CCM) offset 0x204. The AES in addition to the DES, SHA/MD5 and CRC can also be clock gated as a group by setting the D0 bit in the **CRC and Cryptographic Modules (DCGCCM)** register, System Control Module offset 0x874.

### 13.2.6 Hardware Requests

The AES module can assert a  $\mu$ DMA request for context in, context out, input data, or output data read. The **AES uDMA Interrupt Mask (AES\_DMAIM)** register can be set to generate interrupts during the following events:

- Context In  $\mu$ DMA request (AES0 Cin)
- Context Out  $\mu$ DMA request (AES0 Cout)
- Data In  $\mu$ DMA request (AES0 Din)
- Data Out  $\mu$ DMA request (AES0 Dout)

The AES Module can be programmed to assert an interrupt when the uDMA has completed its last transfer. Please refer to “AES  $\mu$ DMA Interrupt Register Descriptions (CCM Offset)” on page 1001 for more information.

If context and data transfers are to be handled through software, then the **AES Interrupt Enable (AES\_IRQENABLE)**, offset 0x090, can be used to enable interrupt triggering when context out, context in, data in or data out is ready. The **AES Interrupt Status (AES\_IRQSTATUS)**, offset 0x08C, indicates when an interrupt is triggered.

**Table 13-2. Interrupts and Events**

| Event                         | Description              |
|-------------------------------|--------------------------|
| AES_IRQSTATUS[3]: CONTEXT_OUT | Context output interrupt |
| AES_IRQSTATUS[2]: DATA_OUT    | Data output interrupt    |
| AES_IRQSTATUS[1]: DATA_IN     | Data input interrupt     |
| AES_IRQSTATUS[0]: CONTEXT_IN  | Context input interrupt  |

### 13.3 AES Performance Information

Table 13-3 on page 970 lists the performance for all supported key sizes and modes of operations. It assumes that the engine is kept fully utilized (that is, the host is supplying input blocks and retrieving output blocks in such a way that the engine never has to wait for input), and that the previous output has been retrieved before the next output is ready.

**Table 13-3. AES Module Performance (Input/Output Block Size = 128)**

| Key Size | Mode of Operation         | Cycles per Block <sup>a</sup> | Throughput (bits/cycle) |
|----------|---------------------------|-------------------------------|-------------------------|
| 128      | ECB-encrypt / decrypt     | 32                            | 4.00                    |
|          | CBC-decrypt               |                               |                         |
|          | CTR/ICM-encrypt / decrypt |                               |                         |
|          | CFB128-decrypt            |                               |                         |
|          | CBC-encrypt               | 33                            | 3.88                    |
|          | OFB-encrypt / decrypt     |                               |                         |
|          | f8-encrypt / decrypt      |                               |                         |
|          | CFB128-encrypt            |                               |                         |
|          | XTS-encrypt / decrypt     |                               |                         |
|          | GCM-outbound / inbound    |                               |                         |
|          | CCM-encrypt / decrypt     | 66                            | 1.94                    |

|          | f9 <sup>b</sup>           |                               |                         |

**Table 13-3. AES Module Performance (Input/Output Block Size = 128) (continued)**

| Key Size | Mode of Operation         | Cycles per Block <sup>a</sup> | Throughput (bits/cycle) |
|----------|---------------------------|-------------------------------|-------------------------|
| 256      | ECB-encrypt / decrypt     | 44                            | 2.91                    |
|          | CBC-decrypt               |                               |                         |
|          | CTR/ICM-encrypt / decrypt |                               |                         |
|          | CFB128-decrypt            |                               |                         |
|          | CBC-encrypt               | 45                            | 2.84                    |
|          | OFB-encrypt / decrypt     |                               |                         |
|          | f8-encrypt / decrypt      |                               |                         |
|          | CFB128-encrypt            |                               |                         |
|          | XTS-encrypt / decrypt     |                               |                         |
|          | GCM-outbound inbound      |                               |                         |
|          | CCM-encrypt / decrypt     | 90                            | 1.42                    |
|          | CBC-MAC <sup>b</sup>      | 45                            | 2.84                    |
|          | f9 <sup>b</sup>           |                               |                         |

a. Standard Block Size (128 bits)

b. Input Only

The "Cycles per block" numbers do not apply to the first block after selection of a new key and/or mode of operation, or the last block before switching to a new algorithm. The next table indicates the additional clock cycles; required for changing context data.

**Table 13-4. AES Module Packet Mode Switch Overhead**

| New Context                       | Cycles needed for first block/and to finish the last block | Total |
|-----------------------------------|------------------------------------------------------------|-------|
| mode is encrypt                   | 1 / 1                                                      | 2     |
| mode is decrypt, key size is 128  | 32 / 1                                                     | 33    |
| mode is decrypt, key size is 192  | 38 / 1                                                     | 39    |
| mode is decrypt, key size is 256  | 44 / 1                                                     | 45    |
| mode is XTS, key size is 128      | 34 / 1                                                     | 35    |
| mode is XTS, key size is 192      | 40 / 1                                                     | 41    |
| mode is XTS, key size is 256      | 46 / 1                                                     | 47    |
| outbound GCM, AES key size is 128 | 33 <sup>a</sup> / 52                                       | 85    |
| outbound GCM, AES key size is 192 | 39 <sup>a</sup> / 52                                       | 91    |
| outbound GCM, AES key size is 256 | 45 <sup>a</sup> / 52                                       | 97    |
| inbound GCM, AES key size is 128  | 33 <sup>a</sup> / 27                                       | 60    |
| inbound GCM, AES key size is 192  | 39 <sup>a</sup> / 27                                       | 66    |
| inbound GCM, AES key size is 256  | 45 <sup>a</sup> / 27                                       | 72    |
| outbound CCM, AES key size is 128 | 33 <sup>b</sup> / 33                                       | 66    |
| outbound CCM, AES key size is 192 | 39 <sup>b</sup> / 39                                       | 78    |
| outbound CCM, AES key size is 256 | 45 <sup>b</sup> / 45                                       | 90    |
| inbound CCM, AES key size is 128  | 33 <sup>b</sup> / 33                                       | 66    |
| inbound CCM, AES key size is 192  | 39 <sup>b</sup> / 39                                       | 78    |

**Table 13-4. AES Module Packet Mode Switch Overhead (continued)**

| New Context                      | Cycles needed for first block/and to finish the last block | Total |
|----------------------------------|------------------------------------------------------------|-------|
| inbound CCM, AES key size is 256 | 45 <sup>b</sup> / 45                                       | 90    |

- a. Numbers for regular GCM mode (H is precalculated and Y0-encrypted need to be calculated internally using the new IV). If H needs to be calculated by the core (complete GCM mode), this number needs to be doubled. If Y0-encrypted is not calculated (forced to zero, such that the hash result is not encrypted) this number is zero.
- b. Numbers for regular CCM mode. Dependent on the AAD length it is possible that one additional encryption needs to be done to finalize the AAD authentication; if the additional operation is required, this number needs to be doubled.

## 13.4 AES Module Programming Guide

### 13.4.1 AES Low - Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the AES Module.

#### 13.4.1.1 Global Initialization

The following list describes the requirements for initializing the AES and surrounding modules when AES is used for the first time after a device reset.

1. When reset has completed, enable the AES by setting the R0 bit in the **CRC and Cryptographic Modules Run Mode Clock Gating Control (RCGCCM)**, System Control offset 0x674. When the R0 bit is set in the **CRC and Cryptographic Modules Peripheral Ready (PRCCM)**, System Control offset 0xA74 register, the AES is powered and ready to be configured.
2. Configure the AES  $\mu$ DMA channels for Context In, Context Out, Data In, and/or Data Out by programming the appropriate encoding value in the **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA module, offset 0x510. For more information on how to program channel assignments as well as enabling burst and the configured channels, refer to "Micro Direct Memory Access ( $\mu$ DMA)" on page 677.
3. Execute a software reset by setting the SOFTRESET bit in the **AES\_SYSCONFIG** register. When reset is complete, the RESETDONE bit reads as 1 in the **AES\_SYSSTATUS** register.
4. If the AES channels are configured in the  $\mu$ DMA, enable the required AES DMA requests by programming bits [9:5] of the **AES\_SYSCONFIG** register, in addition to the completion interrupts in the **AES DMA Interrupt Mask (AES\_DMAIM)** register, CCM offset 0x020.
5. Specify the size of the keys by programming the KEY\_SIZE bit field in the **AES\_CTRL** register.
6. Load **AES Key 1 (AES\_KEY1\_n)** register.
7. Load **AES Key 2 (AES\_KEY2\_n)** register if it is used by the configuration mode. Refer to Table 13-6 on page 980 for information regarding which configuration modes require a load to this register.
8. Configure the AES for the appropriate encryption/decryption mode (see the section called "Subsequence: Initialize CCM AES Core Mode" on page 973 through the section called "Subsequence: Initialize CBC AES Core Mode" on page 974).
9. Select encryption or decryption by programming the DIRECTION bit in the **AES Control (AES\_CTRL)** register, offset 0x050.

### 13.4.1.2 Initialization Subsequence

The following sections list the initialization subsequences for the available encryption/decryption modes:

#### ***Subsequence: Initialize CCM AES Core Mode***

The CCM mode initialization is as follows:

1. Define the width of the length field and the length of the authentication field by programming the CCM\_L and CCM\_M bit fields in the **AES\_CTRL** register at offset 0x050.
2. Enable counter mode by setting the CTR bit in the **AES\_CTRL** register.
3. Load the authentication data length in the AUTH field of the **AES Authentication Data Length (AES\_AUTH\_LENGTH)** register at offset 0x05C.
4. Select the IV counter by programming the CTR\_WIDTH field in the **AES\_CTRL** register.
5. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

#### ***Subsequence: Initialize GCM AES Core Mode***

The following steps to enable GCM mode is as follows:

1. Enable counter mode by setting the CTR bit in the **AES\_CTRL** register.
2. Load the authentication data length in the AUTH field of the **AES Authentication Data Length (AES\_AUTH\_LENGTH)** register at offset 0x05C.
3. Select the IV counter by programming the CTR\_WIDTH field in the **AES\_CTRL** register.
4. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

#### ***Subsequence: Initialize CBC-MAC AES Core Mode***

To initialize CBC-MAC Mode:

1. Enable CBC-MAC Mode by setting the CBCMAC bit in the **AES\_CTRL** register.
2. Select encryption mode by setting the DIRECTION bit in the **AES\_CTRL** register at offset 0x050.
3. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

#### ***Subsequence: Initialize F9 AES Core Mode***

The steps for configuring the AES for F9 mode is as follows:

1. Enable F9 Mode by setting the F9 bit in the **AES\_CTRL** register.
2. Set the key size to 128 bits by programming the KEY\_SIZE field to 0x1 in the **AES\_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

#### ***Subsequence: Initialize F8 AES Core Mode***

The steps for configuring the AES for F8 mode is as follows:

1. Enable F8 Mode by setting the F8 bit in the **AES\_CTRL** register.
2. Select the counter width by programming the CTR\_WIDTH field in the **AES\_CTRL** register.
3. Set the key size to 128 bits by setting the KEY\_SIZE field to 0x1 in the **AES\_CTRL** register.
4. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

***Subsequence: Initialize XTS AES Core Mode***

The steps for XTS mode configuration are as follows:

1. Enable XTS Mode by configuring the XTS field in the **AES\_CTRL** register.
2. If the XTS field in the **AES\_CTRL** register indicates that the AAD length is required, load the AAD length in the **AES\_AUTH\_LENGTH** register.
3. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

***Subsequence: Initialize CFB AES Core Mode***

To initialize the AES code for CFB mode:

1. Enable CFB Mode by setting the CFB bit in the **AES\_CTRL** register.
2. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

***Subsequence: Initialize ICM AES Core Mode***

To initialize the AES code for ICM mode:

1. Enable ICM Mode by setting the ICM bit in the **AES\_CTRL** register.
2. Configure for a 16-bit counter by programming the CTR\_WIDTH to 0x0 in the **AES\_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

***Subsequence: Initialize CTR AES Core Mode***

To initialize CTR mode:

1. Enable CTR Mode by setting the CTR bit in the **AES\_CTRL** register.
2. Select counter width by programming the CTR\_WIDTH in the **AES\_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

***Subsequence: Initialize CBC AES Core Mode***

To configure CBC mode:

1. Enable CBC Mode by setting the MODE bit in the **AES\_CTRL** register.
2. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

### 13.4.1.3 Operational Modes Configuration

#### AES Polling Mode

##### Main Sequence: AES Polling Mode

Figure 13-12 on page 975 shows AES polling mode. The registers used in AES polling mode are:

- AES Data RW Plaintext/Ciphertext 0 (AES\_DATA\_IN\_0) registers, offset 0x060 to 0x06C
- AES Control (AES\_CTRL) register, offset 0x050
- AES Hash Tag Out 0 (AES\_TAG\_OUT\_0), offset 0x070

Figure 13-12. AES Polling Mode

#### AES Interrupt Mode

The application can use software interrupts to control the flow of Context In, Context Out, Data In, and Data Out requests. To enable these interrupts:

1. Once the device has been initialized, following the initialization sequences described in “Global Initialization” on page 972 and “Initialization Subsequence” on page 973, the application can enable the AES module interrupts through the **AES Interrupt Enable (AES\_IRQENABLE)** register, offset 0x090. If all four interrupts must be enabled, the application can write 0x0000.000F to the **AES\_IRQENABLE** register.
2. Load the input buffers, **AES\_DATA\_IN\_n**, with data.

**Note:** If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, AES  $\mu$ DMA Mode should be used and the bits in the **AES\_IRQENABLE** register should be cleared.

#### **AES DMA Mode**

When AES DMA Mode is enabled, the **AES\_IRQENABLE** register should be cleared. To enable the  $\mu$ DMA to transfer data follow these steps:

1. Once the AES module has been initialized, enable the AES module  $\mu$ DMA channels by programming the **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA module. Further  $\mu$ DMA configuration guidelines are available in the “Micro Direct Memory Access ( $\mu$ DMA)” on page 677.
2. Configure the dma\_done interrupts by programming the **AES DMA Masked Interrupt Status (AES\_DMAMIS)** register, at CCM offset 0x028.
3. Enable the  $\mu$ DMA channels in the AES by programming the  $\mu$ DMA enable bits in the **AES System Configuration (AES\_SYSCONFIG)** register, offset 0x084.
4. The input buffer registers, **AES\_DATA\_IN\_n**, at offsets 0x060 to 0x06C, are loaded.

#### **13.4.1.4 AES Events Servicing**

##### ***Interrupt Servicing***

This section describes the event servicing of the module. Figure 13-13 on page 977 shows the AES interrupt service. The registers used during event servicing are:

- **AES\_IRQSTATUS**
- **AES\_KEY1\_n**
- **AES\_KEY2\_n**
- **AES\_IV\_IN\_n**
- **AES\_DATA\_IN\_n**
- **AES\_TAG\_OUT\_n**
- **AES\_IRQENABLE**

Figure 13-13. AES Interrupt Service

## 13.5 Register Map

Table 13-5 on page 977 lists the AES registers. The AES Module comprises registers that exist at an offset relative to the AES Module base address and a small set of AES  $\mu$ DMA registers that exist at an offset relative to an Encryption Control Module base address. The AES Module register offsets are relative to the base address 0x4403.6000. The AES  $\mu$ DMA interrupt registers are offset are relative to the base address 0x4403.0000.

Table 13-5. AES Register Map

| Offset                                          | Name       | Type | Reset       | Description | See page |
|-------------------------------------------------|------------|------|-------------|-------------|----------|
| <b>AES Module Registers (AES Module Offset)</b> |            |      |             |             |          |
| 0x000                                           | AES_KEY2_6 | RW   | 0x0000.0000 | AES Key 2_6 | 980      |
| 0x004                                           | AES_KEY2_7 | RW   | 0x0000.0000 | AES Key 2_7 | 980      |
| 0x008                                           | AES_KEY2_4 | RW   | 0x0000.0000 | AES Key 2_4 | 980      |

Table 13-5. AES Register Map (continued)

| Offset | Name            | Type | Reset       | Description                        | See page |
|--------|-----------------|------|-------------|------------------------------------|----------|
| 0x00C  | AES_KEY2_5      | RW   | 0x0000.0000 | AES Key 2_5                        | 980      |
| 0x010  | AES_KEY2_2      | RW   | 0x0000.0000 | AES Key 2_2                        | 980      |
| 0x014  | AES_KEY2_3      | RW   | 0x0000.0000 | AES Key 2_3                        | 980      |

## 13.6 AES Register Descriptions

This section lists and describes the AES registers, in numerical order by address offset.

**Register 1: AES Key 2\_6 (AES\_KEY2\_6), offset 0x000**

**Register 2: AES Key 2\_7 (AES\_KEY2\_7), offset 0x004**

**Register 3: AES Key 2\_4 (AES\_KEY2\_4), offset 0x008**

**Register 4: AES Key 2\_5 (AES\_KEY2\_5), offset 0x00C**

**Register 5: AES Key 2\_2 (AES\_KEY2\_2), offset 0x010**

**Register 6: AES Key 2\_3 (AES\_KEY2\_3), offset 0x014**

**Register 7: AES Key 2\_0 (AES\_KEY2\_0), offset 0x018**

**Register 8: AES Key 2\_1 (AES\_KEY2\_1), offset 0x01C**

**Register 9: AES Key 1\_6 (AES\_KEY1\_6), offset 0x020**

**Register 10: AES Key 1\_7 (AES\_KEY1\_7), offset 0x024**

**Register 11: AES Key 1\_4 (AES\_KEY1\_4), offset 0x028**

**Register 12: AES Key 1\_5 (AES\_KEY1\_5), offset 0x02C**

**Register 13: AES Key 1\_2 (AES\_KEY1\_2), offset 0x030**

**Register 14: AES Key 1\_3 (AES\_KEY1\_3), offset 0x034**

**Register 15: AES Key 1\_0 (AES\_KEY1\_0), offset 0x038**

**Register 16: AES Key 1\_1 (AES\_KEY1\_1), offset 0x03C**

This register contains the 32-bit key data for the AES module. This value can be expanded to 256-bits depending on the mode of operation. Table 13-6 on page 980 describes the type of key that is held in register.

**Note:** Reads return zeros.

**Table 13-6. AES Key Register Descriptions**

| Register Name | Address Offset | Description                                                                                       |
|---------------|----------------|---------------------------------------------------------------------------------------------------|
| AES_KEY2_6    | 0x000          | Secure XTS second key / CBC-MAC third key                                                         |
| AES_KEY2_7    | 0x004          | Secure XTS second key (MSW for 256-bit key) / CBC-MAC third key (MSW)                             |
| AES_KEY2_4    | 0x008          | Secure XTS / CCM second key / CBC-MAC third key (LSW)                                             |
| AES_KEY2_5    | 0x00C          | Secure XTS second key (MSW for 192-bit key) / CBC-MAC third key                                   |
| AES_KEY2_2    | 0x010          | Secure XTS / CCM / CBC-MAC second key / Hash Key input                                            |
| AES_KEY2_3    | 0x014          | Secure XTS second key (MSW for 128-bit key) + CCM/CBC-MAC second key (MSW) / Hash Key input (MSW) |
| AES_KEY2_0    | 0x018          | Secure XTS / CCM / CBC-MAC second key (LSW) / Hash Key input (LSW)                                |
| AES_KEY2_1    | 0x01C          | Secure XTS / CCM / CBC-MAC second key / Hash Key input                                            |
| AES_KEY1_6    | 0x020          | Secure Key (LSW for 256-bit key)                                                                  |
| AES_KEY1_7    | 0x024          | Secure Key (MSW for 256-bit key)                                                                  |
| AES_KEY1_4    | 0x028          | Secure Key (LSW for 192-bit key)                                                                  |
| AES_KEY1_5    | 0x02C          | Secure Key (MSW for 192-bit key)                                                                  |

Table 13-6. AES Key Register Descriptions (*continued*)

| Register Name | Address Offset | Description                      |
|---------------|----------------|----------------------------------|
| AES_KEY1_2    | 0x030          | Secure Key                       |
| AES_KEY1_3    | 0x034          | Secure Key (MSW for 128-bit key) |
| AES_KEY1_0    | 0x038          | Secure Key (LSW for 128-bit key) |
| AES_KEY1_1    | 0x03C          | Secure Key                       |

## AES Key (AES\_KEYn\_n)

Base 0x4403.6000

Offset 0x000

Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset      | Description                                                                |
|-----------|------|------|------------|----------------------------------------------------------------------------|
| 31:0      | KEY  | RW   | 0x00000000 | Key Data<br>This register contains the 32-bit key data for the AES module. |

**Register 17: AES Initialization Vector Input 0 (AES\_IV\_IN\_0), offset 0x040**

**Register 18: AES Initialization Vector Input 1 (AES\_IV\_IN\_1), offset 0x044**

**Register 19: AES Initialization Vector Input 2 (AES\_IV\_IN\_2), offset 0x048**

**Register 20: AES Initialization Vector Input 3 (AES\_IV\_IN\_3), offset 0x04C**

This register contains the initialization vector input.

AES Initialization Vector Input (AES\_IV\_IN\_n)

Base 0x4403.6000  
Offset 0x040  
Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset       | Description                                                                                                                                                                                                                      |
|-----------|------|------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0      | DATA | RW   | 0x0000.0000 | Initialization Vector Input<br>This field contains the initialization input vector. The least significant word (LSW) is represented in register <b>AES_IV_IN_0</b> and the most significant word is stored in <b>AES_IV_IN_3</b> |

**Register 21: AES Control (AES\_CTRL), offset 0x050**

This register determines the mode of operation of the AES Engine.

**AES Control (AES\_CTRL)**

## Register 22: AES Crypto Data Length 0 (AES\_C\_LENGTH\_0), offset 0x054

## Register 23: AES Crypto Data Length 1 (AES\_C\_LENGTH\_1), offset 0x058

**AES Crypto Data Length n (AES\_C\_LENGTH\_n)** registers (LSW and MSW) store the cryptographic data length in bytes for all modes. The **AES\_C\_LENGTH\_0** register stores the most significant word and the **AES\_C\_LENGTH\_1** register stores the least significant word. Once processing with this context is started, this length decrements to zero. Data lengths up to  $(2^{61} - 1)$  bytes are allowed. For GCM, any value up to 236 - 32 bytes can be used. This is because a 32-bit counter mode is used; the maximum number of 128-bit blocks is  $2^{32} - 2$ , resulting in a maximum number of bytes of  $2^{36} - 32$ . A write to this register triggers the engine to start using this context. This is valid for all modes except GCM and CCM. Note that for the combined modes, this length does not include the authentication only data; the authentication length is specified in the **AES\_AUTH\_LENGTH** register below. All modes must have a length greater than 0. For the combined modes, it is permissible to have one of the lengths equal to zero. For the basic encryption modes (ECB/CBC/CTR/ICM/CFB128) it is permissible to program zero to the length field; in that case the length is assumed infinite. All data must be byte (8-bit) aligned; bit aligned data streams are not supported by the AES Engine.

**Note:** For a Host read operation, these registers return all zeroes.

### AES Crypto Data Length (AES\_C\_LENGTH\_n)

Base 0x4403.6000  
Offset 0x054  
Type RW, reset 0x0000.0000

## Register 24: AES Authentication Data Length (AES\_AUTH\_LENGTH), offset 0x05C

The **AES Authentication Data Length (AES\_AUTH\_LENGTH)** register stores the authentication data length in bytes for combined modes only (GCM or CCM). Supported AUTH lengths for CCM are from 0 to  $(2^{16} - 28)$  bytes. For GCM any value up to  $(2^{32} - 1)$  bytes can be used. Once processing with this context is started, this length decrements to zero. A write to this register triggers the engine to start using this context for GCM and CCM. For XTS, this register is optionally used to load *j*. Loading of *j* is only required if *j*  $\neq$  0. *j* is a 28-bit value and must be written to bits [31-4] of this register. *j* represents the sequential number of the 128-bit block inside the data unit. For the first block in a unit, this value is zero. It is not required to provide a *j* for each new data block within a unit. Note that it is possible to start with a *j* unequal to zero.

**Note:** For a Host read operation, these registers return all-zeroes..

### AES Authentication Data Length (AES\_AUTH\_LENGTH)

Base 0x4403.6000  
Offset 0x05C  
Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset      | Description                                                                                                              |

**Register 25: AES Data RW Plaintext/Ciphertext 0 (AES\_DATA\_IN\_0), offset 0x060**

**Register 26: AES Data RW Plaintext/Ciphertext 1 (AES\_DATA\_IN\_1), offset 0x064**

**Register 27: AES Data RW Plaintext/Ciphertext 2 (AES\_DATA\_IN\_2), offset 0x068**

**Register 28: AES Data RW Plaintext/Ciphertext 3 (AES\_DATA\_IN\_3), offset 0x06C**

The **AES Data RW Plaintext/Ciphertext n (AES\_DATA\_IN\_n)** registers are used to read and write plaintext/ciphertext. The **AES\_DATA\_IN\_0** register contains the most significant word; the **AES\_DATA\_IN\_3** register contains least significant word.

**Note:** The **AES\_DATA\_IN\_0** register acts as a FIFO and shifts data into the other **AES\_DATA\_IN\_n** registers.

**Register 37: AES Interrupt Enable (AES\_IRQENABLE), offset 0x090**

This register contains an enable bit for each unique interrupt generated by the module. It matches the layout of **AES\_IRQSTATUS** register. An interrupt is enabled when the bit in this register is set to 1. An interrupt that is enabled is propagated to the NVIC controller. All AES software interrupts need to be enabled explicitly by writing this register.

**Note:** If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, AES  $\mu$ DMA Mode should be used and the bits in the **AES\_IRQENABLE** register should be cleared.

**AES Interrupt Enable (AES\_IRQENABLE)**

**13.7 AES μDMA Interrupt Register Descriptions (CCM Offset)**

This section lists and describes the AES μDMA registers, in numerical order by address offset. Registers in this section are relative to the base address of 0x4403.0000.

**Register 39: AES DMA Interrupt Mask (AES\_DMAIM), offset 0x020**

The **AES DMA Interrupt Mask (AES\_DMAIM)** register controls interrupt behavior and is used to program which interrupts are suppressed.

**AES DMA Interrupt Mask (AES\_DMAIM)**

Base 0x4403.0000  
Offset 0x020  
Type RW, reset 0x0000.0000

**Register 40: AES DMA Raw Interrupt Status (AES\_DMARIS), offset 0x024**

The **AES DMA Raw Interrupt Status (AES\_DMARIS)** register contains the raw interrupt status. If any of these bits read 1, the processor is interrupted if the corresponding masked interrupt status bit is set to '1.'

**AES DMA Raw Interrupt Status (AES\_DMARIS)**

## 14 Data Encryption Standard Accelerator (DES)

The DES module provides hardware accelerated data encryption and decryption functions. The module runs either the single DES or the triple DES (3DES) algorithm in compliance with the [FIPS 46-3 standard](#) and supports electronic codebook (ECB), cipher block chaining (CBC), and cipher feedback (CFB) modes of operation. It does not support the output feedback (OFB) mode of operation in hardware.

The purpose of the DES algorithm is to encrypt (encipher) or decrypt (decipher) binary coded information. Encrypting data converts it to an unintelligible form called cipher text. Decrypting cipher text converts the data back to its original form called plaintext. DES is a symmetrical algorithm in that the encryption and decryption keys are identical. Each triple DES encrypt/decrypt operation is a compound of DES encrypt and decrypt operations.

The DES accelerator includes the following main features:

- DES/3DES encryption and decryption.
- Feedback modes: ECB, CBC, CFB
- Host interrupt or  $\mu$ DMA driven modes of operation.  $\mu$ DMA support for data and context in/result out
- Fully synchronous design
- Internal wide-bus interface

### 14.1 DES Functional Description

The DES module is an efficient implementation of a DES block cipher. Block ciphers, as opposed to stream ciphers, operate on blocks of plain text and cipher text. The DES block size is 8-byte. The DES key consists of 64 binary digits, but only 56 bits are actually used directly by the algorithm. The other 8 bits are used for error detection.

The 64-bit block of input data to be enciphered is initially permuted, then passed through 16 iterations of a calculation that uses a cipher function and finally permuted to the inverse of the initial permutation. At each of the 16 iterations, a 48-bit key computed from the 64-bit input key is applied to one of the 32-bit sub-blocks of the 64-bit input block using the cipher function. The 48-bit key value changes for each iteration. The result of the cipher function is a 32-bit sub-block, which is concatenated with the second 32-bit input sub-block. The resulting 64-bit output block of each iteration feeds back as the input of the next iteration. To decipher, it is only necessary to apply the same algorithm to the enciphered message block, taking care that each iteration of the computation will use the same 48-bit key which was used during enciphering.

The triple DES is the DES used three times in a row (also known as DES-EDE). It uses three keys key1, key2, and key3, so that key length is 168 bits effective: a 64-bit block plaintext is encrypted with key1, decrypted with key2, and encrypted with key3, and a 64-bit ciphertext is decrypted with key1, encrypted with key2, and decrypted with key3.

There are three keying options defined in ANSI X9.52 for DES-EDE:

- The three keys key1, key2, and key3 are independent.
- key1 and key2 are independent, but key1 = key3
- key1 = key2 = key3

The first option provides highest level of security; the last option is compatible with single DES. See Table 14-1 on page 1009 for key use.

**Table 14-1. Key Repartition**

| Mode           | Key1_L | Key1_H | Key2_L | Key2_H | Key3_L | Key3_H |
|----------------|--------|--------|--------|--------|--------|--------|
| 64-bit (DES)   | √      | √      | X      | X      | X      | X      |
| 192-bit (3DES) | √      | √      | √      | √      | √      | √      |

ECB, CBC, and CFB modes can be used with DES and 3DES modes.

## 14.2 DES Block Diagram

The module architecture consists of primary blocks, as shown in Figure 14-1 on page 1009. The DES module includes a register interface, and a  $\mu$ DMA and interrupt interface.

Depending of the availability of context and data, the DES engine is automatically triggered to process the data. The DES engine is directly connected to the context and data registers such that it can immediately start processing when all data is available.

Packets (blocks of 64 bits) must be parsed into blocks and sequentially fed into the DES, which can buffer the block currently being processed as well as an additional block that may be queued in advance.

**Figure 14-1. DES Block Diagram**

### 14.2.1 $\mu$ DMA Control

The  $\mu$ DMA and interrupt request logic is controlled by the DES Engine. The DES Engine can have multiple  $\mu$ DMA request signals active in parallel.

There are three DMA channels available:

- DMA context in - Request a new context (DES0 Cin)
- DMA data in - Request input data (DES0 Din)
- DMA data out - Request output data read (DES0 Dout)

### **14.2.2 Interrupt Control**

There is one interrupt for the DES that is sent to the interrupt controller. This interrupt is an OR of the enabled interrupt bits in the **DES Interrupt Status (DES\_IRQSTATUS)** register. These bits are enabled through the **DES Interrupt Enable (DES\_IRQENABLE)** register. The following events can generate an interrupt bit to be set in the **DES\_IRQSTATUS** register. These are:

- New context input required
- Data input required
- Data output ready

### **14.2.3 Register Interface**

The Register Interface block performs all address decoding and control; however, not all registers are available in this block. The context and data input registers are in the DES engine.

### **14.2.4 DES Engine**

The DES buffered engine consists of the following major functional blocks:

- Cipher core: the DES algorithm
- Mode control FSM: manages the data flow to and from the DES buffered engine and starts each encrypt/decrypt operation
- DES feedback mode block: the logic that implements the various feedback modes supported by the DES buffered engine

#### **14.2.4.1 Mode Control FSM**

The Mode control FSM manages the data flow to and from the DES engine. This block also sends a start pulse to the encrypt/decrypt core and triggers the core to use the new mode keys when a new context is needed. This module also controls the 3DES operation, such that the DES core module is triggered three times (with different keys) before the result data becomes available.

#### **14.2.4.2 DES Feedback Mode Block**

The DES feedback mode block buffers the input and output blocks and contains all logic to implement the 3DES and various feedback modes. See the FIPS-81 document for details on the ECB, CBC, and CFB modes of operation.

By itself, the DES cipher core outputs data compliant for ECB encryption. However, most applications use DES with feedback. Feedback provides additional security by randomizing repeated patterns in the plain text, which could otherwise be exploited to attack the cipher text. The DES buffered engine supports ECB, CBC, and CFB modes of operations for the DES and 3DES algorithm.

3DES mode performs the DES algorithm three times on a single block and uses a different key for each invocation of the DES algorithm, greatly increasing security of the cipher text but at the cost

of a 3x reduction in throughput. The DES buffered engine implements a 3DES logic wrapper around the 2-round DES core, enabling seamless 3DES encryption.

#### 14.2.4.3 DES Cipher Core

The DES cipher core implements the DES algorithm as specified in the FIPS 46-3. The core operates on the input block and performs the required substitution, shift, and mix operations. The core also applies the correct key-scheduling.

Inherently, considerable parallelism is possible with the DES algorithm. This is exploited in two ways. For high performance, the 64 bits composing the data block are processed concurrently (4-round implementation). For low gate-count, resources are shared on both the main data and key paths (1-round implementation).

A fundamental component of the DES algorithm is the substitution box (S-Box). The S-Box provides a unique 4-bit output for each 6-bit input. The S-Box design is a primary factor for both performance and gate count. The DES Cipher Core has a standard lookup table S-Box that allows room for the synthesizer to optimize on timing or gate count.

### 14.3 Software Reset

Table 14-2 on page 1011 lists the resets used in the DES module.

**Table 14-2. DES Reset Description**

| Type     | Name                           | Source   | Description                                                                                                                             |
|----------|--------------------------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Hardware | DES_RST                        | PRCM     | Global reset                                                                                                                            |
| Software | DES_SYSCONFIG [1]<br>SOFTRESET | Internal | Starts the soft reset sequence. When the DES_SYSSTATUS/DES_P_SYSSTATUS[0] RESETDONE bit goes to 1, the soft reset sequence is finished. |

### 14.4 DES Supported Modes of Operation

#### 14.4.1 ECB Feedback Mode

Figure 14-2 on page 1012 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output of the cryptographic core is passed directly to the output buffer. For decryption the DES core operates in reverse, this means the decrypt key sequence is used for the data processing, where encryption uses the encrypt key sequence.

**Figure 14-2. DES - ECB Feedback Mode****14.4.1.1 CBC Feedback Mode**

Figure 14-3 on page 1012 shows the CBC feedback mode of operation, where the input data is XORed with the initialization vector (IV) before it is passed to the basic crypto core. The output of the crypto core is passed directly to the output buffer. For decryption the operation is reversed, resulting in an XOR at the output of the crypto core.

**Figure 14-3. DES3DES - CBC Feedback Mode****14.4.1.2 CFB Feedback Mode**

Figure 14-4 on page 1013 shows the CFB mode of operation for encryption and decryption. The input for the crypto core is the IV; the result is XORed with the data. The result is fed back via the IV register, as the next input for the crypto core. The decrypt operation is reversed, but the crypto core is still performing an encryption.

**Figure 14-4. DES3DES-CFB Feedback Mode**

## 14.5 DES Module Programming Guide -Low Level Programming Models

### 14.5.1 Surrounding Modules Global Initialization

#### 14.5.1.1 Main Sequence - DES Global Initialization

This procedure initializes the DES after a POR.

**Table 14-3. DES Global Initialization**

| Step                                         | Register/Bit Field/Programming Model | Value |
|----------------------------------------------|--------------------------------------|-------|
| Execute software reset.                      | DES_SYSCONFIG[1] SOFTRESET           | 0x1   |
| Wait for reset to complete                   | DES_SYSSTATUS[0] RESETDONE           | = 0x1 |
| Select force idle mode                       | DES_SYSCONFIG[3:2] SIDLE             | 0x0   |
| Select the algorithm type (DES or 3DES)      | See the programming models           |       |
| Select the operating mode (ECB, CBC or CFB). | DES_CTRL[5:4] MODE                   | -     |
| IF: ECB operating mode not selected.         | DES_CTRL[5:4] MODE                   | ≠ 0x0 |
| Load the initialization vector LSW.          | DES_IV_L[31:0] IV_L                  | -     |
| Load the initialization vector MSW.          | DES_IV_H[31:0] IV_H                  | -     |
| Define the cryptographic data length.        | DES_LENGTH[31:0] LENGTH              | -     |
| ENDIF                                        |                                      |       |
| Select encryption or decryption.             | DES_CTRL[2] DIRECTION                | -     |

#### 14.5.1.2 Subsequence - Configure the DES Algorithm Type

This subsequence details the DES algorithm type settings.

**Table 14-4. DES Algorithm Type Configuration**

| Step                  | Register/Bit Field/Programming Model | Value |
|-----------------------|--------------------------------------|-------|
| Load key 1 LSW.       | DES_KEY1_L[31:0] KEY1_L              | -     |
| Load key 1 MSW.       | DES_KEY1_H[31:0] KEY1_H              | -     |
| Select DES algorithm. | DES_CTRL[3] TDES                     | 0x0   |

### 14.5.1.3 Subsequence - Configure the 3DES Algorithm Type

This subsequence details the 3DES algorithm type settings.

**Table 14-5. 3DES Algorithm Type Configuration**

| Step                   | Register/Bit Field/Programming Model | Value |
|------------------------|--------------------------------------|-------|
| Load key 1 LSW.        | DES_KEY1_L[31:0] KEY1_L              | -     |
| Load key 1 MSW.        | DES_KEY1_H[31:0] KEY1_H              | -     |
| Load key 2 LSW.        | DES_KEY2_L[31:0] KEY2_L              | -     |
| Load key 2 MSW.        | DES_KEY2_H[31:0] KEY2_H              | -     |
| Load key 3 LSW.        | DES_KEY3_L[31:0] KEY3_L              | -     |
| Load key 3 MSW.        | DES_KEY3_H[31:0] KEY3_H              | -     |
| Select 3DES algorithm. | DES_CTRL[3] TDES                     | 0x1   |

## 14.5.2 Operational Modes Configuration

### 14.5.2.1 Main Sequence - DES Polling Mode

Figure 14-5 on page 1015 shows DES polling mode. The registers used in DES polling mode are: DES\_DATA\_L, DES\_DATA\_H, and DES\_CTRL.

**Figure 14-5. DES Polling Mode**

### 14.5.2.2 DES Interrupt Mode

Table 14-6 on page 1015 lists the DES interrupt mode steps.

**Table 14-6. DES Interrupt Mode**

| Step                                     | Register/Bit Field/Programming Model | Value |
|------------------------------------------|--------------------------------------|-------|
| Enable DES module interrupts.            | DES_IRQENABLE[2:0]                   | 0x7   |
| Load the input buffer data LSW register. | DES_DATA_L[31:0] DATA_L              | -     |
| Load the input buffer data HSW register. | DES_DATA_H[31:0] DATA_H              | -     |

### 14.5.2.3 DES Interrupt DMA Mode

Table 14-7 on page 1015 lists the DES DMA mode steps.

**Table 14-7. DES DMA Mode**

| Step                                     | Register/Bit Field/Programming Model | Value |
|------------------------------------------|--------------------------------------|-------|
| Enable DES module DMA requests.          | DES_SYSCONFIG[7:5]                   | 0x7   |
| Load the input buffer data LSW register. | DES_DATA_L[31:0] DATA_L              | -     |

**Table 14-7. DES DMA Mode (continued)**

| Step                                     | Register/Bit Field/Programming Model | Value |
|------------------------------------------|--------------------------------------|-------|
| Load the input buffer data HSW register. | DES_DATA_H[31:0] DATA_H              | -     |

### 14.5.3 DES Events Servicing

#### 14.5.3.1 Interrupt Servicing

This section describes the event servicing of the module. Figure 14-6 on page 1016 shows the DES interrupt service. The registers used during event servicing are: DES\_IRQSTATUS, DES\_DATA\_L, and DES\_DATA\_H.

**Figure 14-6. DES Interrupt Service**

#### 14.5.3.2 Context Input Event Servicing

This section describes the context input event servicing of the module, as shown in Figure 14-7 on page 1017. The registers used during event servicing are: DES\_CTRL, DES\_SYSCONFIG, DES\_KEY1\_L, DES\_KEY1\_H, DES\_KEY2\_L, DES\_KEY2\_H, DES\_KEY3\_L, DES\_KEY3\_H, DES\_IV\_L, DES\_IV\_H, and DES\_LENGTH.

Figure 14-7. DES Context Input Event Service

## 14.6 Register Map

Table 14-8 on page 1017 lists the DES registers. The DES Module comprises registers that exist at an offset relative to the DES Module base address and a small set of DES  $\mu$ DMA registers that exist at an offset relative to an Encryption Control Module base address. The DES Module register offsets are relative to the base address 0x4403.8000. The Encryption Control register offsets are relative to the base address 0x4403.0000.

**Note:** The DES registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed and can corrupt register contents.

Table 14-8. DES Register Map

| Offset                                          | Name       | Type | Reset       | Description                   | See page |
|-------------------------------------------------|------------|------|-------------|-------------------------------|----------|
| <b>DES Module Registers (DES Module Offset)</b> |            |      |             |                               |          |
| 0x000                                           | DES_KEY3_L | RW   | 0x0000.0000 | DES Key 3 LSW for 192-Bit Key | 1019     |
| 0x004                                           | DES_KEY3_H | RW   | 0x0000.0000 | DES Key 3 MSW for 192-Bit Key | 1019     |
| 0x008                                           | DES_KEY2_L | RW   | 0x0000.0000 | DES Key 2 LSW for 128-Bit Key | 1019     |

Table 14-8. DES Register Map (*continued*)

| Offset                                                                                          | Name          | Type | Reset       | Description                     | See page |
|-------------------------------------------------------------------------------------------------|---------------|------|-------------|---------------------------------|----------|
| 0x00C                                                                                           | DES_KEY2_H    | RW   | 0x0000.0000 | DES Key 2 MSW for 128-Bit Key   | 1019     |
| 0x010                                                                                           | DES_KEY1_L    | RW   | 0x0000.0000 | DES Key 1 LSW for 64-Bit Key    | 1019     |
| 0x014                                                                                           | DES_KEY1_H    | RW   | 0x0000.0000 | DES Key 1 MSW for 64-Bit Key    | 1019     |
| 0x018                                                                                           | DES_IV_L      | RW   | 0x0000.0000 | DES Initialization Vector       | 1020     |
| 0x01C                                                                                           | DES_IV_H      | RW   | 0x0000.0000 | DES Initialization Vector       | 1021     |
| 0x020                                                                                           | DES_CTRL      | RW   | 0x8000.0000 | DES Control                     | 1022     |
| 0x024                                                                                           | DES_LENGTH    | RW   | 0x0000.0000 | DES Cryptographic Data Length   | 1023     |
| 0x028                                                                                           | DES_DATA_L    | RW   | 0x0000.0000 | DES LSW Data RW                 | 1024     |
| 0x02C                                                                                           | DES_DATA_H    | RW   | 0x0000.0000 | DES MSW Data RW                 | 1025     |
| 0x030                                                                                           | DES_REVISION  | RO   | 0x0000.0021 | DES Revision Number             | 1026     |
| 0x034                                                                                           | DES_SYSCONFIG | RW   | 0x0000.0001 | DES System Configuration        | 1027     |
| 0x038                                                                                           | DES_SYSSTATUS | RO   | 0x0000.0001 | DES System Status               | 1029     |

## 14.7 DES Register Description

This section lists and describes the DES registers, in numerical order by address offset.

**Register 1: DES Key 3 LSW for 192-Bit Key (DES\_KEY3\_L), offset 0x000**

**Register 2: DES Key 3 MSW for 192-Bit Key (DES\_KEY3\_H), offset 0x004**

**Register 3: DES Key 2 LSW for 128-Bit Key (DES\_KEY2\_L), offset 0x008**

**Register 4: DES Key 2 MSW for 128-Bit Key (DES\_KEY2\_H), offset 0x00C**

**Register 5: DES Key 1 LSW for 64-Bit Key (DES\_KEY1\_L), offset 0x010**

**Register 6: DES Key 1 MSW for 64-Bit Key (DES\_KEY1\_H), offset 0x014**

The function of each of these registers is described in more detail in Table 14-9 on page 1019.

**Note:** A read of this register returns all zeros.

**Table 14-9. DES Key Register Mapping**

| Register Name | Address Offset | Description                           |
|---------------|----------------|---------------------------------------|
| DES_KEY3_L    | 0x00000000     | KEY3 (LSW) for 192-bit key            |
| DES_KEY3_H    | 0x00000004     | KEY3 (MSW) for 192-bit key            |
| DES_KEY2_L    | 0x00000008     | KEY2 (LSW) for 192-bit key            |
| DES_KEY2_H    | 0x0000000C     | KEY2 (MSW) for 192-bit key            |
| DES_KEY1_L    | 0x00000010     | KEY1 (LSW) for 64-bit key/192-bit key |
| DES_KEY1_H    | 0x00000014     | KEY1 (MSW) for 64-bit key/192-bit key |

#### DES Key for 192-Bit Key (DES\_KEYn\_n)

Base 0x4403.8000

Offset 0x000

Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset      | Description |
|-----------|------|------|------------|-------------|
| 31:0      | KEY  | RW   | 0x00000000 | Key Data    |

Register 7: DES Initialization Vector (DES\_IV\_L), offset 0x018

Least significant word of the initialization vector.

DES Initialization Vector (DES\_IV\_L)

Base 0x4403.8000  
Offset 0x018  
Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset      | Description                                    |
|-----------|------|------|------------|------------------------------------------------|
| 31:0      | IV_L | RW   | 0x00000000 | Initialization vector for CBC, CFB modes (LSW) |

Register 8: DES Initialization Vector (DES\_IV\_H), offset 0x01C

Most significant word of the initialization vector.

DES Initialization Vector (DES\_IV\_H)

Base 0x4403.8000  
Offset 0x01C  
Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset      | Description                                    |
|-----------|------|------|------------|------------------------------------------------|
| 31:0      | IV_H | RW   | 0x00000000 | Initialization vector for CBC, CFB modes (MSW) |

**Register 9: DES Control (DES\_CTRL), offset 0x020**

## DES Control (DES\_CTRL)

Base 0x4403.8000

Offset 0x020

Type RW, reset 0x8000.0000

|       |          |    |    |    |    |    |    |    |    |    |      |    |      |           |             |              |

**Register 10: DES Cryptographic Data Length (DES\_LENGTH), offset 0x024**

Indicates the cryptographic data length in bytes for all modes. Once processing is started with this context, this length decrements to zero. Data lengths up to (232 - 1) bytes are allowed. A write to this register triggers the engine to start using this context.

**Note:** A read of this register returns all zeros.

DES Cryptographic Data Length (DES\_LENGTH)

Base 0x4403.8000  
Offset 0x024  
Type RW, reset 0x0000.0000

| Bit/Field | Name   | Type | Reset      | Description                                      |
|-----------|--------|------|------------|--------------------------------------------------|
| 31:0      | LENGTH | RW   | 0x00000000 | Cryptographic data length in bytes for all modes |

**Register 11: DES LSW Data RW (DES\_DATA\_L), offset 0x028**

Data register (LSW) to read/write encrypted/decrypted data.

## DES LSW Data RW (DES\_DATA\_L)

Base 0x4403.8000

Offset 0x028

Type RW, reset 0x0000.0000

| Bit/Field | Name   | Type | Reset      | Description                         |
|-----------|--------|------|------------|-------------------------------------|
| 31:0      | DATA_L | RW   | 0x00000000 | Data for encryption/decryption, LSW |

Register 12: DES MSW Data RW (DES\_DATA\_H), offset 0x02C

Data register (MSW) to read/write encrypted/decrypted data.

DES MSW Data RW (DES\_DATA\_H)

Base 0x4403.8000  
Offset 0x02C  
Type RW, reset 0x0000.0000

| Bit/Field | Name   | Type | Reset      | Description                         |
|-----------|--------|------|------------|-------------------------------------|
| 31:0      | DATA_H | RW   | 0x00000000 | Data for encryption/decryption, MSW |

Register 13: DES Revision Number (DES\_REVISION), offset 0x030

Revision Number

DES Revision Number (DES\_REVISION)

Base 0x4403.8000  
Offset 0x030  
Type RO, reset 0x0000.0021

| Bit/Field | Name     | Type | Reset       | Description     |
|-----------|----------|------|-------------|-----------------|
| 31:0      | REVISION | RO   | 0x0000.0021 | Revision number |

**Register 14: DES System Configuration (DES\_SYSCONFIG), offset 0x034**

System Configuration of DES module

**Note:** After one operation has completed, the **DES\_SYSCONFIG** register must be cleared and re-configured for the next operation to ensure proper DMA and data operation functionality.

## DES System Configuration (DES\_SYSCONFIG)

Base 0x4403.8000  
Offset 0x034  
Type RW, reset 0x0000.0001

## Value Description

0 Reset is not complete

1 Reset done

**Register 16: DES Interrupt Status (DES\_IRQSTATUS), offset 0x03C**

This register indicates the interrupt status. If one of the interrupt bits is set the interrupt output will be asserted.

**DES Interrupt Status (DES\_IRQSTATUS)**

Base 0x4403.8000

Offset 0x03C

Type RO, reset 0x0000.0000

**14.8 DES  $\mu$ DMA Interrupt Register Descriptions (CCM Offset)**

This section lists and describes the DES  $\mu$ DMA registers, in numerical order by address offset. Registers in this section are relative to the base address of 0x4403.0000.

**Register 19: DES DMA Interrupt Mask (DES\_DMAIM), offset 0x030**

The **DES DMA Interrupt Mask** register control interrupt behavior and are used to program which interrupts are suppressed.

**Register 20: DES DMA Raw Interrupt Status (DES\_DMARIS), offset 0x034**

The **DES DMA Raw Interrupt Status** register contains the raw interrupt status. If any of these bits read 1, the processor is interrupted if the corresponding masked interrupt status bit is set to 1.

**DES DMA Raw Interrupt Status (DES\_DMARIS)**

Base 0x4403.0000

Offset 0x034

Type RO, reset 0x0000.0000

## 15 SHA/MD5 Accelerator

The SHA/MD5 module provides hardware-accelerated hash functions and can run:

- MD5 message digest algorithm developed by Ron Rivest in 1991
- SHA-1 algorithm compliant with the [FIPS 180-3 standard](#)
- SHA-2 (SHA-224 and SHA-256) algorithm compliant with the FIPS 180-3 standard
- Hash message authentication code (HMAC) operation

The algorithms produce a condensed representation of a message or a data file, called digest or signature, which can then be used to verify the message integrity.

- Hashing of 0 to  $2^{33} - 2$  bytes of data (of which  $2^{32} - 1$  bytes are in one pass) using the MD5, SHA-1, SHA-224, or SHA-256 hash algorithm (byte granularity only, no support for bit granularity)
- Automatic HMAC key preprocessing for HMAC keys up to 64 bytes
- Host-assisted HMAC key preprocessing for HMAC keys larger than 64 bytes
- HMAC from precomputes (inner/outer digest) for improved performance on small blocks
- Supports  $\mu$ DMA operation for data and context in/result out transfers
- Supports interrupt to read the digest (signature)

### 15.1 SHA/MD5 Functional Description

#### 15.1.1 SHA/MD5 Block Diagram

Figure 15-1 on page 1038 shows the module architecture, which consists of four primary blocks: the Hash/HMAC engine, the configuration registers and the interface to  $\mu$ DMA and the interrupt handler.

Figure 15-1. SHA/MD5 Module Block Diagram

#### 15.1.1.1 Configuration Registers

The configuration registers contain the following global control and status registers for the SHA/MD5 Module:

- System control register that controls the mode of operation (**SHA\_SYSCONFIG** register)
- μDMA interrupt control registers (**SHA\_DMAIM**, **SHA\_DMARIS**, **SHA\_DMAMIS**, and **SHA\_DMAIC** registers, which reside in the Encryption Control Base address space)
- Interrupt status register (**SHA\_IRQSTATUS** register)
- Enable register (**SHA\_IRQENABLE** register)

#### 15.1.1.2 Hash/HMAC Engine

The Hash/HMAC engine performs the SHA-1, SHA-2, or MD5 hash computation. When loaded with a data block, and optionally an intermediate digest, it independently performs the hash computation (64 or 80 rounds, depending on the algorithm) on that data block.

It can also start from the specified initial digest values instead of a loaded intermediate. Furthermore, it can perform the IPAD and OPAD XORs for MAC operations. The hash core does not perform any hash padding; this is performed in the Host Interface Block, where the data input registers are located. A loaded data block must always be a full 64 bytes (512 bits) long.

#### 15.1.1.3 Hash Core Control

When the hash core is idle or done, a new hash operation can be started. Any additional information needed by the hash core (mode of operation, data to process, input digest if not starting from algorithm constants or continuing) must be provided by programming the SHA registers before the core can accept the operation.

#### 15.1.1.4 Host Interface Bank

The Host Interface Bank can access the hash core for hashing individual 64-byte hash blocks. The Host Interface Bank contains registers such as the data FIFO (**SHA Data n Input (SHA\_DATA\_n\_IN)** registers), the **SHA Inner Digest x (SHA\_IDIGEST\_X)** registers, and several control and status registers.

The Host Interface Block contains all relevant control logic for performing hash and HMAC computations on large (that is, larger than one hash block) blocks of data, including hash padding, final hash, and outer hash. It provides the necessary flow control to the SHA  $\mu$ DMA and interrupt interface.

#### 15.1.2 Power Management

To save power, the application can disable the clock to the SHA/MD5 module when not in use. The SHA/MD5 is clock gated by setting the SHACFG bit in the **Cryptographic Modules Clock Gating Request (CCMCGREQ)** register, CCM offset 0x204. The SHA in addition to the AES, DES, and Enhanced CRC can also be clock gated as a group by setting the D0 bit in the **CRC and Cryptographic Modules Deep-Sleep Mode Clock Gating Control (DCGCCCM)** register, System Control Module offset 0x874.

#### 15.1.3 Reset Management

To perform a software reset of the SHA module, write a 1 to the SOFTRESET bit in the **SHA System Configuration (SHA\_SYSCONFIG)** register. The RESETDONE bit in the **SHA System Status (SHA\_SYSSTATUS)** register indicates that the software reset is complete when its value is 1. When the software reset completes, the SOFTRESET bit in the **SHA\_SYSCONFIG** register is automatically reset. Software must ensure that the software reset completes before doing any operations.

The behavior of the software reset is the same as the hardware reset, except that the software reset bit resets this module without affecting the reset core domain of the entire device.

#### 15.1.4 $\mu$ DMA and Interrupt Requests

The SHA/MD5 module can operate in  $\mu$ DMA mode where the module can assert a  $\mu$ DMA request for context in, context out, or data input. The  $\mu$ DMA signals that can be generated are:

- Context In  $\mu$ DMA request (SHA/MD5 0 Cin): Request for Key, Digest, Mode and LENGTH information
- Context Out  $\mu$ DMA request (SHA/MD5 0 Cout): Request for read from HMAC
- Data In  $\mu$ DMA request (SHA/MD5 0 Din): Request input data in multiples of 16 bytes

The SHA/MD5 Module be programmed to assert an interrupt when the  $\mu$ DMA has completed its last transfer by programming the **SHA DMA Interrupt Mask (SHA\_DMAIM)**, at the CRC and Cryptographic Modules (CCM) offset 0x010. The **SHA DMA Raw Interrupt Status (SHA\_DMARIS)** register, at CCM offset 0x014, indicates when the  $\mu$ DMA has completed and can be cleared by the **SHA DMA Interrupt Clear (SHA\_DMAIC)** register at CCM offset 0x01C.

**Note:** The SHA module can only be accessed through privileged mode. If the  $\mu$ DMA is used for SHA transfers, then the  $\mu$ DMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

If context and data transfers are to be handled through software in Interrupt Mode, then the **SHA Interrupt Enable (SHA\_IRQENABLE)**, offset 0x11C, can be used to enable interrupt triggering

when context out, context in, data in or data out is ready. The **SHA Interrupt Status (SHA\_IRQSTATUS)**, offset 0x118, indicates when an interrupt is triggered.

**Note:** If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, SHA  $\mu$ DMA Mode should be used and the bits in the **SHA\_IRQENABLE** register should be cleared.

**Table 15-1. Interrupts and Events**

| Event                         | Description              |
|-------------------------------|--------------------------|
| SHA_IRQSTATUS[3]: CONTEXT_OUT | Context output interrupt |
| SHA_IRQSTATUS[1]: DATA_IN     | Data input interrupt     |
| SHA_IRQSTATUS[0]: CONTEXT_IN  | Context input interrupt  |

### 15.1.5 Operation Description

The SHA/MD5 Module can run the SHA-1, SHA-224, SHA-256, and MD5 algorithms, depending on the value of the ALGO bit field in the **SHA Mode (SHA\_MODE)** register, offset 0x044, as listed in Table 15-2 on page 1040.

**Table 15-2. SHA/MD5 Module Algorithm Selection**

| ALGO Field Value in SHA_MODE Register | Description                |
|---------------------------------------|----------------------------|
| 0x0                                   | MD5 algorithm selected     |
| 0x1                                   | SHA-1 algorithm selected   |
| 0x2                                   | SHA-224 algorithm selected |
| 0x3                                   | SHA-256 algorithm selected |

#### 15.1.5.1 SHA Mode

##### *Starting a New Hash*

To start a new hash, follow these steps:

1. Set the ALGO bitfield in the **SHA\_MODE** register, at offset 0x044, to 0x1, 0x2, or 0x3 to select SHA-1, SHA-224, or SHA-256, respectively.
2. Set the ALGO\_CONSTANT bit in the **SHA\_MODE** register to 1 to initialize all **SHA Inner/Outer Digest n** registers from **SHA\_ODIGEST\_A/SHA\_IDIGEST\_A** to **SHA\_ODIGEST\_H/SHA\_IDIGEST\_H** with their default values specified by the algorithm, and set the **SHA\_DIGESTCOUNT** register to 0.
3. Set the CLOSE\_HASH bit of the **SHA Mode (SHA\_MODE)** register to let the SHA engine do the padding. If the Hash is computed in one shot, the length of the message can be any value up to 128 MB. To process an intermediate Hash digest, the CLOSE\_HASH bit is set to 0, in which case the packets hashed must be 64 bytes; the last packet must be hashed with the CLOSE\_HASH bit set to 1.
4. Specify the LENGTH field in the **SHA Length (SHA\_LENGTH)** register of the hash data to process in bytes.

After the configuration is complete, the INPUT\_READY status bit equals 1 in the **SHA Interrupt Status (SHA\_IRQSTATUS)** register (regardless of whether or not the M\_INPUT\_READY bit in the **SHA\_IRQENABLE** register is set. When this bit is set, it indicates the SHA engine can receive the

data to process. Data must be written to the 16 x 32-bit **SHA\_DATA\_n\_IN** registers that provide storage for one 64-byte block of data. Unless the **CLOSE\_HASH** bit is set, all of the **SHA\_DATA\_n\_IN** input buffers must be filled. Data can be written by single write accesses to the 16 registers from a processor or by a DMA transfer.

For  $\mu$ DMA transfers, the **DMA\_EN** bit must be set in the **SHA\_SYSCONFIG** register and the appropriate mask bits must be set in the **SHA\_DMAIM** register before starting the new hash. Note that if the  $\mu$ DMA is used for transfers, the **SHA\_IRQENABLE** register should be clear so all interrupts are generated through the  $\mu$ DMA interrupt registers.

The  $\mu$ DMA must be configured to transfer 16 data words of 32 bits each time it is triggered by a  $\mu$ DMA request from the SHA/MD5 Module. The 16 data words written are sent to the 16 **SHA\_DATA\_n\_IN** registers.

The module detects that a 64-byte block is available, and then moves the data to a working register space for processing and asserts the **INPUT\_READY** bit in the **SHA\_IRQSTATUS** register to 1. If the **DMA\_EN** bit in the **SHA\_SYSCONFIG** register has been set to 1, a new  $\mu$ DMA request triggers a new block transfer; otherwise, the processor polls the **INPUT\_READY** bit and writes the 16 data words of 32 bits when it equals 1.

This operation is repeated until the length of the message to hash is reached. The **OUTPUT\_READY** bit in the **SHA\_IRQSTATUS** register then indicates that the hash operation is complete. If the **IT\_EN** bit in the **SHA\_SYSCONFIG** register is set, an interrupt (active low) is also generated to indicate the hash completion.

The processor can then read the eight digest registers A through H that contain the hash and/or HMAC result. If the hash is an intermediate result of a larger hash, the digest count register must also be read and saved.

**Note:** The number of digest registers used depends on the algorithm selected for the SHA/MD5 Module (MD5, SHA-1, SHA-224, or SHA-256), as shown in Table 15-3 on page 1041 and Table 15-4 on page 1042

**Table 15-3. Outer Digest Registers**

| Register      | Address | MD5<br>(Read/Write)      | SHA-1<br>(Read/Write)     | SHA-2 (Read/Write)     | HMAC Key<br>Processing (write) |
|---------------|---------|--------------------------|---------------------------|------------------------|--------------------------------|
| SHA_ODIGEST_A | 0x000   | Outer digest<br>[127:96] | Outer digest<br>[159:128] | Outer digest [255:224] | HMAC Key [31:0]                |

| SHA_IDIGEST_D | 0x02C   | Inner digest<br>[31:0]   | Inner digest<br>[63:32]   | Inner digest<br>[127:96]  | Inner digest<br>[159:128] | HMAC key<br>[383:352]          |
| SHA_IDIGEST_E | 0x030   |                          | Inner<br>digest[31:0]     | Inner digest<br>[95:64]   | Inner digest<br>[127:96]  | HMAC key<br>[415:384]          |
| SHA_IDIGEST_F | 0x034   |                          |                           | Inner digest<br>[63:32]   | Inner digest [95:64]      | HMAC key<br>[447:416]          |
| SHA_IDIGEST_G | 0x038   |                          |                           | Inner digest [31:0]       | Inner digest [63:32]      | HMAC key<br>[479:448]          |
| SHA_IDIGEST_H | 0x03C   |                          |                           |                           | Inner digest[31:0]        | HMAC key<br>[511:480]          |

**Note:** Inner digests are initial, intermediate, and result digests.

#### Outer Digest Registers

The **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_H** registers are relevant only for HMAC operations; the contents are ignored for hash operations.

Before writing to the digest registers, the operation must be configured in the **SHA Mode (SHA\_MODE)** register. For HMAC operations without key processing, the **HMAC\_KEY\_PROC** bit must be clear in the **SHA\_MODE** register before starting operations. Once the algorithm has been programmed in the **SHA\_MODE** register, only the relevant digest registers for the selected algorithm must be written:

- **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_D** registers for MD5
- **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_E** registers for SHA-1
- **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_H** registers for SHA-2 (224 to 256)

When HMAC key processing is enabled (**HMAC\_KEY\_PROC**=1), these registers must be written with the lower 256 bits of the HMAC key to be processed in little-endian format (first byte of key string in bits [7:0]).

**Note:** If the HMAC key is less than 512 bits, it must be properly padded with zeros: all 16 HMAC key registers must be written explicitly; the core does not pad. Additionally, if the HMAC key is larger than 512 bits, the host must perform a preprocessing step to reduce it to one 512-bit block. This involves hashing the large key and padding the hash result with zeros until it is 512 bits wide.

The computed outer digest can be read from these registers when the **SHA Interrupt Status (SHA\_IRQSTATUS)** register when the **OUTPUT\_READY** bit has been set indicating that the operation is done.

**Note:** If no HMAC key processing is performed, the value read is identical to the value written initially. The MD5 outer digest is available from registers **SHA\_ODIGEST\_A** to

**SHA\_ODIGEST\_D**, the SHA-1 outer digest from registers **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_E**, and the SHA-224 and SHA-256 outer digest from registers **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_H**.

**Note:** The HMAC key is not preserved. If another block must be authenticated using the same key, the key must be reloaded by the host. If the same key must be used many times, it is advisable to do a HMAC key processing-only pass to obtain the inner and outer digest precomputes and load these precomputes for subsequent passes (only the inner digest must be reloaded if the outer digest is not modified by the host), because this saves two hash blocks worth of computation time.

### **Inner Digest Registers**

The **SHA\_IDIGEST\_A** to **SHA\_IDIGEST\_H** registers are used for HMAC and hash operations.

The inner/initial digest for HMAC and hash continue operations (HMAC\_KEY\_PROC = 0 and ALGO\_CONSTANT = 0) must be written to these registers before starting the operation by writing to the **SHA\_MODE** register. Only the relevant digest registers for the selected algorithm must be written:

- **SHA\_IDIGEST\_A** to **SHA\_IDIGEST\_D** registers for MD5
- **SHA\_IDIGEST\_A** to **SHA\_IDIGEST\_E** registers for SHA-1
- **SHA\_IDIGEST\_A** to **SHA\_IDIGEST\_H** registers for SHA-2

When ALGO\_CONSTANT = 1 in the **SHA\_MODE** register, the **SHA Inner Digest n (SHA\_IDIGEST\_n)** registers do not need to be written by the application because they are overwritten with the appropriate algorithm constants.

When HMAC\_KEY\_PROC is 1, these registers must be written with the upper 256 bits of the HMAC key to be processed in little-endian format (first byte of key string in bits [7:0]).

**Note:** If the HMAC key is less than 512 bits, it must be properly padded with zeros: all 16 HMAC key registers must be written explicitly; the core does not pad. Additionally, if the HMAC key is larger than 512 bits, the host must perform a preprocessing step to reduce it to one 512-bit block. This involves hashing the large key and padding the hash result with zeros until it is 512 bits wide.

The order of the bytes within the digest is such that it can be fed back unmodified into the little-endian data input when preprocessing HMAC keys larger than 64 bytes, or it can typically be inserted unmodified into a little-endian data stream (for example, IPSEC packets), regardless of the selected algorithm.

**Note:** The HMAC key or inner digest is not preserved. If another block must be authenticated using the same key, the key or inner digest must be reloaded by the host. If the same key must be used many times, it is advisable to do a HMAC key processing-only pass to obtain the inner and outer digest precomputes and load these precomputes for subsequent passes (only the inner digest must be reloaded if the outer digest is not modified by the host), because this saves two hash blocks worth of computation time.

### **Closing a Hash**

The amount of data to hash is not necessarily a multiple of 64 bytes. The CLOSE\_HASH bit in the **SHA\_MODE** register is set to append padding so that the message size becomes a multiple of 64 bytes. Consequently, a minimum of 9 bytes must be added to the message. Nine bytes is the minimum number of bytes that contains the minimum 65-bit padding specified by FIPS 180-1.

If the size of the last block of data is less than or equal to 55 bytes, no additional 64-byte block is required. However, if the last block of data contains more than 55 bytes, an extra 64-byte block must be added to make the padding as specified by FIPS 180-1. This extra block is added automatically by the hardware; thus, the module is fed with a 64-byte block of data. However, appending a pad on the last block of data can result in the creation of an extra 64-byte block.

The one or two last blocks that contain the padding are processed in the same way as the other blocks. Hash completion is then indicated in the same way as for a new hash, and the hash result can be read in the digest registers. The **SHA\_DIGESTCOUNT** register returns restored Digest Count + Length when it is read, and hashing completes.

Assuming a message of 129 bytes, Table 15-5 on page 1044 shows the SHA digest for three passes. Table 15-6 on page 1044 shows the SHA digest for one pass.

**Table 15-5. SHA Digest Processed in Three Passes**

|             | Digest (A to E)            | SHA_DIGESTCOUNT | SHA_MODE and SHA_LENGTH                                                                              | SHA_DATA_n_IN              |
|-------------|----------------------------|-----------------|------------------------------------------------------------------------------------------------------|----------------------------|
| First pass  |                            |                 | WRITE:<br>LENGTH=64<br>ALGO (dependent on the algorithm to apply)<br>ALGO_CONSTANT=1<br>CLOSE_HASH=0 | First 64 bytes of message  |
| Second pass | Round 1 digest calculation | WRITE: 64       | WRITE:<br>LENGTH=64<br>ALGO (dependent on the algorithm to apply)<br>ALGO_CONSTANT=0<br>CLOSE_HASH=0 | Second 64 bytes of message |
| Third pass  | Round 2 digest calculation | WRITE: 128      | Write:<br>LENGTH=1<br>ALGO (dependent on the algorithm to apply)<br>ALGO_CONSTANT=0<br>CLOSE_HASH=1  | Last byte of message       |
|             | Final digest               | READ: 129       |                                                                                                      |                            |

If the three passes are not performed in succession, the digest registers must be saved and restored for the next use of the SHA/MD5 engine. If the rounds are performed consecutively, there is no need to do anything with the digest registers.

**Table 15-6. SHA Digest Processed in One Pass**

|            | Digest (A to E) | SHA_DIGEST_COUNT | SHA_MODE and SHA_LENGTH                                                                               | SHA_DATA_n_IN             |
|------------|-----------------|------------------|-------------------------------------------------------------------------------------------------------|---------------------------|
| First pass |                 |                  | WRITE:<br>LENGTH=129<br>ALGO (dependent on the algorithm to apply)<br>ALGO_CONSTANT=1<br>CLOSE_HASH=1 | First 64 bytes of message |

**Table 15-6. SHA Digest Processed in One Pass (continued)**

|  | Digest (A to E)            | SHA_DIGEST_COUNT | SHA_MODE and SHA_LENGTH | SHA_DATA_n_IN              |
|--|----------------------------|------------------|-------------------------|----------------------------|
|  | Round 1 digest calculation |                  |                         | Second 64 bytes of message |
|  | Round 2 digest calculation |                  |                         | Last byte of message       |
|  | Final digest               | Read: 129        |                         |                            |

### 15.1.5.2 MD5 Mode

#### **Starting a New Hash**

To start a new hash, perform the following steps:

1. Set the ALGO bit field in the **SHA\_MODE** register to 0x0 to select the MD5 algorithm.
2. Set the ALGO\_CONSTANT bit to 1 in the **SHA\_MODE** register to initialize all digest registers from **SHA\_ODIGEST\_A/SHA\_IDIGEST\_A** to **SHA\_ODIGEST\_H/SHA\_IDIGEST\_H** with default values specified by the algorithm, and set the **SHA\_DIGESTCOUNT** register to 0.
3. Specify the LENGTH field in the **SHA\_LENGTH** register of the hash data to process in bytes.
4. Set the CLOSE\_HASH bit in the **SHA\_MODE** register to let the SHA/MD5 engine do the padding. If MD5 is computed in one shot, the length of the message can be any value up to . To process an intermediate MD5 digest, the CLOSE\_HASH bit is set to 0, in which case packets to be hashed must be 64 bytes; the last packet must be hashed with the CLOSE\_HASH bit set to 1.

After the configuration is complete, the hash engine can receive the data to process (the INPUT\_READY bit is 1 in the **SHA\_IRQSTATUS** register). Data must be written to the 16 x 32-bit **SHA\_DATA\_n\_IN** registers that provide storage for one 64-byte block of data. Unless the CLOSE\_HASH bit is set in the **SHA\_MODE** register, the **SHA\_DATA\_n\_IN** 64-byte input buffer must be filled. Data can be written by single write transactions to the 16 registers from a processor or by a  $\mu$ DMA transfer.

For a  $\mu$ DMA transfer, the SDAM\_EN bit must be set in the **SHA\_SYSCONFIG** register before starting the new hash and the  $\mu$ DMA channel for SHA/MD5 0 Data In Request must be configured. The  $\mu$ DMA must be configured to the appropriate hash transfer size. See “Micro Direct Memory Access ( $\mu$ DMA)” on page 677 for more information on programming the  $\mu$ DMA. A  $\mu$ DMA done is asserted after the last **SHA\_DATA\_n\_IN** register is filled..

The module detects that a 64-byte block is available, and then moves the data to a working register space for processing and sets the INPUT\_READY bit to 1 in the **SHA\_IRQSTATUS** register. If the DMA\_EN bit is set in the **SHA\_SYSCONFIG** register, then a new  $\mu$ DMA request triggers a new block transfer; otherwise, the processor polls the INPUT\_READY bit in the **SHA\_IRQSTATUS** register and writes the 16 data words of 32 bits when it equals 1.

This operation repeats until the length of the message to hash is reached. The OUTPUT\_READY bit in the **SHA\_IRQSTATUS** register then indicates that the hash operation is complete. If the IT\_EN bit in the **SHA\_SYSCONFIG** register is set, an interrupt (active low) is also generated to indicate the hash completion.

### Closing a Hash

The amount of data to hash is not necessarily a multiple of 64 bytes. In this case, the CLOSE\_HASH bit in the SHA\_MODE register must be set to append padding so that the message size becomes a multiple of 64 bytes. See the previous MD5 algorithm for more information on padding.

The module is fed with a 64-byte block of data, as long as enough data is available. However, a pad is appended on the last block of data. This can result in the creation of an extra 64-byte block.

The one or two last blocks that contain the padding are processed the same way as the other blocks. Hash completion is then indicated the same way as for a new hash, and the 128-bit result can be read in the digest registers. The **SHA\_DIGESTCOUNT** register returns restored digest count and length when it is read, and hashing completes.

#### 15.1.5.3 Generating an Software Interrupt

If the IT\_EN bit is 1 in the **SHA\_SYSCONFIG** register, an interrupt is generated at the completion of the hash by the following steps:

1. Receive last block of data (= 64 bytes). (The number of data bytes defined by the **SHA\_LENGTH** register is received in the digest registers, from **SHA\_ODIGEST\_A/SHA\_IDIGEST\_A** to **SHA\_ODIGEST\_H/SHA\_IDIGEST\_H**).
2. If required, apply padding to the last block of data.
3. Hash the last block of data (80 cycles in SHA-1 mode and 64 cycles in MD5, SHA-224, and SHA-256 modes).
4. If required, add an extra 64-byte block of data to complete the padding.
5. Hash this extra block of data (80 cycles in SHA-1 mode and 64 cycles in MD5, SHA-224, and SHA-256 modes).
6. An interrupt is generated (active low).

#### 15.1.6 SHA/MD5 Performance Information

The following table lists the performance for all supported key sizes and modes of operations. It assumed that the engine is kept fully utilized (that is, the host is supplying input block and retrieving output blocks in such a way, that the engine never has to wait for input) and that the previous output has been retrieved before the next output is ready.

Maximum throughput does not include per operation overhead cycles, as the impact on the throughput depends on the size of the block being processed, and would be negligible for large blocks anyway.

**Table 15-7. SHA/MD5 Performance**

| Operation | Algorithm | Cycles per operation | Cycles per block |
|-----------|-----------|----------------------|------------------|
| Hash      | MD5       | 0 / 65               | 65               |
|           | SHA-1     | 0 / 81               | 81               |
|           | SHA-224   | 0 / 65               | 65               |
|           | SHA-256   | 0 / 65               | 65               |

**Table 15-7. SHA/MD5 Performance (continued)**

| Operation             | Algorithm | Cycles per operation | Cycles per block |
|-----------------------|-----------|----------------------|------------------|
| HMAC from Key         | MD5       | 196 / 261            | 65               |
|                       | SHA-1     | 244 / 325            | 81               |
|                       | SHA-224   | 196 / 261            | 65               |
|                       | SHA-256   | 196 / 261            | 65               |
|                       | MD5       | 66 / 131             | 65               |
| HMAC from precomputes | SHA-1     | 82 / 163             | 81               |
|                       | SHA-224   | 66 / 131             | 65               |
|                       | SHA-256   | 66 / 131             | 65               |

**Note:** An extra block needs to be processed if the length of the data block to be hashed module 64 is 0 or equal to 56.

## 15.1.7 SHA/MD5 Programming Guide

This section covers the hardware programming sequences for configuration and use of the SHA/MD5 Module.

### 15.1.7.1 Global Initialization

#### *Surrounding Modules Global Initialization*

This section identifies the requirements for initializing the surrounding modules when the SHAM is used for the first time after a device reset.

1. When reset has completed, enable the SHA/MD5 Module by setting the R0 bit in the **CRC And Cryptographic Modules Run Mode Clock Gating Control (RCGCCM)** register, System Control offset 0x674. When the R0 bit is set in the **CRC and Cryptographic Modules (PRCCM)** register, System Control offset 0xA74 register, the SHA/MD5 Module is powered and ready to be configured.
2. Configure the SHA  $\mu$ DMA channels for Context In, Context Out, Data In, and/or Data Out by programming the appropriate encoding value in the **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA module, offset 0x510. For more information on how to program channel assignments as well as enabling burst and the configured channels, refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 677.
3. Execute a software reset by setting the SOFTRESET bit in the **SHA\_SYSCONFIG** register. When reset is complete, the RESETDONE bit reads as 1 in the **SHA\_SYSSTATUS** register.
4. If the SHA channels are configured in the  $\mu$ DMA, enable the required SHA DMA requests by programming bits [9:5] of the **SHA\_SYSCONFIG** register, in addition to the completion interrupts in the **SHA DMA Interrupt Mask (SHA\_DMAIM)** register, CRC and Cryptographic Modules offset 0x020.

#### *Starting a New HMAC using the SHA-1 Hash Function and HMAC Key Processing*

The following procedure is used to begin a new HMAC operation, starting from initial digest values.

1. Load the key value in the **SHA\_ODIGEST\_A/SHA\_IDIGEST\_A** to **SHA\_ODIGEST\_H/SHA\_IDIGEST\_H** registers.

2. Pad the rest of the SHA\_ODIGEST\_x and SHA\_IDIGEST registers with zeros.
3. Load the message in the **SHA\_DATA\_n\_IN** FIFO registers.
4. Enable HMAC key processing by setting the HMAC\_KEY\_PROC bit in the **SHA\_MODE** register.
5. Select the SHA-1 hash function by programming the ALGO bit in the **SHA\_MODE** register to 0x1.
6. Select the already loaded key by programming the ALGO\_CONSTANT bit in the SHA\_MODE register to 0x0.
7. Set the CLOSE\_HASH bit and the HMAC\_OUTER\_HASH bit in the **SHA\_MODE** register so that appropriate padding is inserted and the outer hash is performed immediately after the inner hash has finished.
8. Program the **SHA\_LENGTH** register with the block length. Writing this register triggers the HMAC engine to begin processing.

**Note:** If more than one pass is used during the process (SHA\_MODE[4] CLOSE\_HASH == 0x0), the block length value must be a 64-byte multiple. From this point, three operational modes are possible to continue with the processing: polling, interrupt, and DMA. For more information, see the Operational Modes Configuration section.

#### ***Subsequence - Continuing a Prior HMAC Using the SHA-1 Hash Function***

The procedure in continues a prior HMAC calculation interrupted from a high priority task.

**Table 15-8. Continuing a Prior HMAC**

| Step                                                                                   | Register/Bit Field/Programming Model | Value |
|----------------------------------------------------------------------------------------|--------------------------------------|-------|
| Load the initial digest for the used hash algorithm.                                   | SHA_IDIGEST_i[31:0] DATA             | -     |
| Restore the digest counter with the value before the switch to the high-priority task. | SHA_DIGEST_COUNT[31:0] COUNT         | -     |
| Use the already loaded in the engine key.                                              | SHA_MODE[5] HMAC_KEY_PROC            | 0x0   |
| Do not use the constants of the selected hash algorithm.                               | SHA_MODE[3] ALGO_CONSTANT            | 0x0   |
| Select the SHA-1 hash algorithm.                                                       | SHA_MODE[2:1] ALGO                   | 0x1   |
| IF: This is the last 64-byte data block from the input message?                        | User decision                        |       |
| Close the hash; an appropriate padding is added.                                       | SHA_MODE[4] CLOSE_HASH               | 0x1   |
| ENDIF                                                                                  |                                      |       |
| Load the block length; this is the trigger to start processing.                        | SHA_LENGTH[31:0] LENGTH              | -     |

**Note:** This initial digest is the intermediate digest from the previous calculation before switching to the high priority task. The value is equal to context1 in .

**Note:** The value is equal to context2 in .

**Note:** The block length is equal to the context3 value in .

#### ***Subsequence - Hashing a Key Bigger than 512 Bits with the SHA-1 Hash Function***

The procedure in creates a hash value from the key in only one pass.

**Table 15-9. SHA-1 Apply on the Key**

| Step                                                               | Register/Bit Field/Programming Model | Value |
|--------------------------------------------------------------------|--------------------------------------|-------|
| Load the first part of the key. (Here, the key is like a message.) | SHA_DATA_n_IN (i = 0 to 15)          | -     |
| Select the SHA-1 hash function.                                    | SHA_MODE[2:1] ALGO                   | 0x1   |
| Select a new hash operation.                                       | SHA_MODE[3] ALGO_CONSTANT            | 0x1   |
| Close the hash; the key is processed in single pass.               | SHA_MODE[4] CLOSE_HASH               | 0x1   |

**Operational Modes Configuration****SHA/MD5 Polling Mode**

Figure 15-2 on page 1049 shows the SHA/MD5 polling mode. SHA/MD5 polling mode uses the following registers: SHA\_IRQSTATUS, SHA\_DATA\_n\_IN, SHA\_ODIGEST\_A, SHA\_DIGEST\_COUNT, and SHA\_LENGTH.

**Figure 15-2. SHA/MD5 Polling Mode****SHA/MD5 Interrupt Mode**

The procedure in configures the SHA/MD5 module to work in interrupt-based mode. (For the interrupt subroutine, see the Interrupt Servicing section.)

**Table 15-10. Interrupt Mode**

| Step                                                    | Register/Bit Field/Programming Model | Value |
|---------------------------------------------------------|--------------------------------------|-------|
| Enable the interrupt request to the Cortex-A8 MPU INTC. | SHA_SYSCONFIG[2] IT_EN               | 0x1   |

**Table 15-10. Interrupt Mode (continued)**

| Step                                                              | Register/Bit Field/Programming Model | Value |
|-------------------------------------------------------------------|--------------------------------------|-------|
| Load the message length; this is the trigger to start processing. | SHA_LENGTH[31:0] LENGTH              | -     |

**SHA/MD5 DMA Mode**

The procedure in configures the SHA/MD5 module to work in DMA-based mode.

**Table 15-11. DMA Mode**

| Step                                                              | Register/Bit Field/Programming Model | Value |
|-------------------------------------------------------------------|--------------------------------------|-------|
| Enable the DMA request to the CDMA controller.                    | SHA_SYSCONFIG[3] DMA_EN              | 0x1   |
| Load the message length; this is the trigger to start processing. | SHA_LENGTH[31:0] LENGTH              | -     |

**SHA/MD5 Event Servicing****Interrupt Servicing**

This section describes the interrupt event servicing of the module. Figure 15-3 on page 1051 shows the interrupt subroutine. The following registers are used in the SHA/MD5 interrupt routine:

SHA\_IRQSTATUS, SHA\_DATA\_n\_IN, SHA\_ODIGEST\_A, SHA\_DIGEST\_COUNT, SHA\_LENGTH, and SHA\_IDIGEST\_A.

Figure 15-3. SHA/MD5 Interrupt Subroutine

## 15.2 SHA/MD5 Register Map

Table 15-12 on page 1051 lists the SHA/MD5 registers. The SHA Module comprises registers that exist at an offset relative to the SHA/MD5 Module base address and a small set of SHA/MD5  $\mu$ DMA interrupt registers that exist at an offset relative to an CRC and Cryptographic Modules base address. The SHA/MD5 Module register offsets are relative to the base address 0x4403.4000. The SHA  $\mu$ DMA offsets are relative to the base address 0x4403.0000 .

Table 15-12. SHA/MD5 Register Map

| Offset                                                  | Name          | Type | Reset       | Description        | See page |
|---------------------------------------------------------|---------------|------|-------------|--------------------|----------|
| <b>SHA/MD5 Module Registers (SHA/MD5 Module Offset)</b> |               |      |             |                    |          |
| 0x000                                                   | SHA_ODIGEST_A | RW   | 0x0000.0000 | SHA Outer Digest A | 1055     |
| 0x004                                                   | SHA_ODIGEST_B | RW   | 0x0000.0000 | SHA Outer Digest B | 1055     |
| 0x008                                                   | SHA_ODIGEST_C | RW   | 0x0000.0000 | SHA Outer Digest C | 1055     |
| 0x00C                                                   | SHA_ODIGEST_D | RW   | 0x0000.0000 | SHA Outer Digest D | 1055     |

Table 15-12. SHA/MD5 Register Map (continued)

| Offset | Name             | Type | Reset       | Description        | See page |
|--------|------------------|------|-------------|--------------------|----------|
| 0x010  | SHA_ODIGEST_E    | RW   | 0x0000.0000 | SHA Outer Digest E | 1055     |

## 15.3 SHA/MD5 Register Descriptions

This section describes the SHA/MD5 registers.

**Note:** The SHA/MD5 registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed and can corrupt register contents.

The first 16 registers of HIB1 are the outer and inner digest registers.

Table 15-13. SHA/MD5 Inner/Outer Digest/HMAC Key Register Mapping

| Register Name | Address Offset | MD5 (read/write)      | SHA-1 (read/write)     | SHA-2 (read/write)     |                        | HMAC key proc (write) |
|---------------|----------------|-----------------------|------------------------|------------------------|------------------------|-----------------------|
| SHA_ODIGEST_A | 0x00000000     | Outer digest [127:96] | Outer digest [159:128] | Outer digest [255:224] |                        | HMAC key [31,0]       |
| SHA_ODIGEST_B | 0x00000004     | Outer digest [95:64]  | Outer digest [127:96]  | Outer digest [223:192] |                        | HMAC key [63,32]      |
| SHA_ODIGEST_C | 0x00000008     | Outer digest [63:32]  | Outer digest [95:64]   | Outer digest [191:160] |                        | HMAC key [95,64]      |
| SHA_ODIGEST_D | 0x0000000C     | Outer digest [31:0]   | Outer digest [63:32]   | Outer digest [159:128] |                        | HMAC key [127,96]     |
| SHA_ODIGEST_E | 0x00000010     |                       | Outer digest [31:0]    | Outer digest [127:96]  |                        | HMAC key [159,128]    |
| SHA_ODIGEST_F | 0x00000014     |                       |                        | Outer digest [95:64]   |                        | HMAC key [191,160]    |
| SHA_ODIGEST_G | 0x00000018     |                       |                        | Outer digest [63:32]   |                        | HMAC key [223,192]    |
| SHA_ODIGEST_H | 0x0000001C     |                       |                        | Outer digest [31:0]    |                        | HMAC key [255,224]    |
| SHA_IDIGEST_A | 0x00000020     | Inner digest [127:96] | Inner digest [159:128] | Inner digest [223:192] | Inner digest [255:224] | HMAC key [287,256]    |
| SHA_IDIGEST_B | 0x00000024     | Inner digest [95:64]  | Inner digest [127:96]  | Inner digest [191:160] | Inner digest [223:192] | HMAC key [319,288]    |
| SHA_IDIGEST_C | 0x00000028     | Inner digest [63:32]  | Inner digest [95:64]   | Inner digest [159:128] | Inner digest [191:160] | HMAC key [351,320]    |

Table 15-13. SHA/MD5 Inner/Outer Digest/HMAC Key Register Mapping (*continued*)

| Register Name | Address Offset | MD5 (read/write)    | SHA-1 (read/write)   | SHA-2 (read/write)    |                        | HMAC key proc (write) |

**Register 17: SHA Digest Count (SHA\_DIGEST\_COUNT), offset 0x040**

This register is written with the initial digest count and can be read to determine the digest count result. Note that for Initial Digest Count writes, bits 5:0 must be zero. This register is written the initial digest byte count when both the HMAC\_KEY\_PROC bit and the ALGO\_CONSTANT bit is zero in the SHA\_MODE register. When either the HMAC\_KEY\_PROC bit or the ALGO\_CONSTANT bit is 1, this register does not need to be written because it is overwritten with 64 or 0 automatically. When starting an HMAC operation from precomputes (HMAC\_KEY\_PROC=0), the value 64 must be written in the **SHA\_DIGESTCOUNT** register. Note that the value written should always be a 64 byte multiple, the lower 6 bits written are ignored. The updated digest byte count (initial digest byte count + bytes processed) can be read from this register when the status register indicates that the operation is done or when a  $\mu$ DMA context out is requested.

**Register 19: SHA Length (SHA\_LENGTH), offset 0x048**

WRITE: Block Length/Remaining Byte Count (bytes) READ: Remaining Byte Count. The value programmed MUST be a 64-byte multiple if Close Hash is set to 0. This register is also the trigger to start processing: once this register is written, the core will commence requesting input data via DMA or IRQ (if programmed length > 0) and start processing. The remaining byte count for the active operation can be read from this register when the interrupt status register indicates that the operation is suspended due to a context switch request.

**SHA Length (SHA\_LENGTH)**

Base 0x4403.4000

Offset 0x048

Register 36: SHA Revision (SHA\_REVISION), offset 0x100

This register provides the unique revision number of the module. This can be used by the driver to determine the capabilities available.

**Register 37: SHA System Configuration (SHA\_SYSCONFIG), offset 0x110**

System configuration register

**Note:** After one operation has completed, the **SHA\_SYSCONFIG** register must be cleared and re-configured for the next operation to ensure proper  $\mu$ DMA and data operation functionality.

## 15.4 SHA/MD5 $\mu$ DMA Control Register Descriptions (Encryption Control Offset)

This section lists and describes the SHA/MD5  $\mu$ DMA registers, in numerical order by address offset. Registers in this section are relative to the Encryption Control base address of 0x4403.0000.

**Note:** The SHA module can only be accessed through privileged mode. If the  $\mu$ DMA is used for SHA transfers, then the  $\mu$ DMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

**Note:** If the application uses SHA  $\mu$ DMA interrupt triggers, the bits in the **SHA\_IRQENABLE** register should be cleared.

**Register 41: SHA DMA Interrupt Mask (SHA\_DMAIM), offset 0x010**

The **SHA DMA Interrupt Mask (SHA\_DMA\_IM)** register controls interrupt behavior and are used to program which interrupts are suppressed.

## 16 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The TM4C129DNCZAD General-Purpose Timer Module (GPTM) contains 16/32-bit GPTM blocks. Each 16/32-bit GPTM block provides two 16-bit timers/counters (referred to as Timer A and Timer B) that can be configured to operate independently as timers or event counters, or concatenated to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger  $\mu$ DMA transfers.

In addition, timers can be used to trigger analog-to-digital conversions (ADC). The ADC trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

The GPT Module is one timing resource available on the Tiva™ C Series microcontrollers. Other timer resources include the System Timer (SysTick) (see 139) and the PWM timer in the PWM module (see “PWM Timer” on page 1739).

The General-Purpose Timer Module (GPTM) contains eight 16/32-bit GPTM blocks with the following functional options:

- Operating modes:
  - 16- or 32-bit programmable one-shot timer
  - 16- or 32-bit programmable periodic timer
  - 16-bit general-purpose timer with an 8-bit prescaler
  - 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
  - 16-bit input-edge count- or time-capture modes with an 8-bit prescaler
  - 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
  - The System Clock or a global Alternate Clock (ALTCLK) resource can be used as timer clock source. The global ALTCLK can be:
    - PIOSC
    - Hibernation Module Real-time clock output (RTCOSC)
    - Low-frequency internal oscillator (LFIOSC)
- Count up or down
- Sixteen 16/32-bit Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)

- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Dedicated channel for each timer
  - Burst request generated on timer interrupt

## 16.1 Block Diagram

In the block diagram, the specific Capture Compare PWM (CCP) pins available depend on the TM4C129DNCZAD device. See Table 16-1 on page 1073 for the available CCP pins and their timer assignments.

Figure 16-1. GPTM Module Block Diagram

Table 16-1. Available CCP Pins

| Timer             | Up/Down Counter | Even CCP Pin | Odd CCP Pin |
|-------------------|-----------------|--------------|-------------|

## 16.2 Signal Description

The following table lists the external signals of the GP Timer module and describes the function of each. The GP Timer signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these GP Timer signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to choose the GP Timer function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 788) to assign the GP Timer signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 741.

## 16.3 Functional Description

The main components of each GPTM block are two free-running up/down counters (referred to as Timer A and Timer B), two prescaler registers, two match registers, two prescaler match registers, two shadow registers, and two load/initialization registers and their associated control functions. The exact functionality of each GPTM is controlled by software and configured through the register interface. Timer A and Timer B can be used individually, in which case they have a 16-bit counting range for the 16/32-bit GPTM blocks. In addition, Timer A and Timer B can be concatenated to provide a 32-bit counting range for the 16/32-bit GPTM blocks. Note that the prescaler can only be used when the timers are used individually.

The available modes for each GPTM block are shown in Table 16-3 on page 1076. Note that when counting down in one-shot or periodic modes, the prescaler acts as a true prescaler and contains the least-significant bits of the count. When counting up in one-shot or periodic modes, the prescaler acts as a timer extension and holds the most-significant bits of the count. In input edge count, input

edge time and PWM mode, the prescaler always acts as a timer extension, regardless of the count direction.

**Table 16-3. General-Purpose Timer Capabilities**

| Mode       | Timer Use    | Count Direction | Counter Size | Prescaler Size <sup>a</sup> |
|------------|--------------|-----------------|--------------|-----------------------------|
| One-shot   | Individual   | Up or Down      | 16-bit       | 8-bit                       |
|            | Concatenated | Up or Down      | 32-bit       | -                           |
| Periodic   | Individual   | Up or Down      | 16-bit       | 8-bit                       |
|            | Concatenated | Up or Down      | 32-bit       | -                           |
| RTC        | Concatenated | Up              | 32-bit       | -                           |
| Edge Count | Individual   | Up or Down      | 16-bit       | 8-bit                       |
| Edge Time  | Individual   | Up or Down      | 16-bit       | 8-bit                       |
| PWM        | Individual   | Down            | 16-bit       | 8-bit                       |

a. The prescaler is only available when the timers are used individually

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 1094), the **GPTM Timer A Mode (GPTMTAMR)** register (see page 1095), and the **GPTM Timer B Mode (GPTMTBMR)** register (see page 1099). When in one of the concatenated modes, Timer A and Timer B can only operate in one mode. However, when configured in an individual mode, Timer A and Timer B can be independently configured in any combination of the individual modes.

### 16.3.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters Timer A and Timer B are initialized to all 1s, along with their corresponding registers:

- Load Registers:
  - **GPTM Timer A Interval Load (GPTMTAILR)** register (see page 1121)
  - **GPTM Timer B Interval Load (GPTMTBILR)** register (see page 1122)
- Shadow Registers:
  - **GPTM Timer A Value (GPTMTAV)** register (see page 1131)
  - **GPTM Timer B Value (GPTMTBV)** register (see page 1132)

The following prescale counters are initialized to all 0s:

- **GPTM Timer A Prescale (GPTMTAPR)** register (see page 1125)
- **GPTM Timer B Prescale (GPTMTBPR)** register (see page 1126)
- **GPTM Timer A Prescale Snapshot (GPTMTAPS)** register (see page 1134)
- **GPTM Timer B Prescale Snapshot (GPTMTBPS)** register (see page 1135)

### 16.3.2 Timer Clock Source

The general purpose timer has the capability of being clocked by either the system clock or an alternate clock source. By setting the ALTCLK bit in the **GPTM Clock Configuration (GPTMCC)**

register, offset 0xFC8, software can select an alternate clock source as programmed in the **Alternate Clock Configuration (ALTCLKCFG)** register, offset 0x138 in the System Control Module. The alternate clock source options available are PIOSC, RTCOSC and LFIOSC. Refer to “System Control” on page 224 for additional information.

**Note:** When the ALTCLK bit is set in the **GPTMCC** register to enable using the alternate clock source, the synchronization imposes restrictions on the starting count value (down-count), terminal value (up-count) and the match value. This restriction applies to all modes of operation. Each event must be spaced by 4 Timer (ALTCLK) clock periods + 2 system clock periods. If some events do not meet this requirement, then it is possible that the timer block may need to be reset for correct functionality to be restored.

Example:  $ALTCLK = T_{PIOSC} = 62.5\text{ns}$  (16Mhz Trimmed)

$T_{hclk} = 1\mu\text{s}$  (1Mhz)

$4 * 62.5\text{ns} + 2 * 1\mu\text{s} = 2.25\mu\text{s}$   $2.25\mu\text{s} / 62.5\text{ns} = 36$  or 0x23

The minimum values for the periodic or one-shot with a match interrupt enabled are:

**GPTMTAMATCHR** = 0x23 **GPTMTAILR** = 0x46

### 16.3.3 Timer Modes

This section describes the operation of the various timer modes. When using Timer A and Timer B in concatenated mode, only the Timer A control and status bits must be used; there is no need to use Timer B control and status bits. The GPTM is placed into individual/split mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 1094). In the following sections, the variable "n" is used in bit field and register names to imply either a Timer A function or a Timer B function. Throughout this section, the timeout event in down-count mode is 0x0 and in up-count mode is the value in the **GPTM Timer n Interval Load (GPTMTnILR)** and the optional **GPTM Timer n Prescale (GPTMTnPR)** registers, with the exception of RTC mode.

#### 16.3.3.1 One-Shot/Periodic Timer Mode

The selection of one-shot or periodic mode is determined by the value written to the TnMR field of the **GPTM Timer n Mode (GPTMTnMR)** register (see page 1095). The timer is configured to count up or down using the TnCDIR bit in the **GPTMTnMR** register.

When software sets the TnEN bit in the **GPTM Control (GPTMCTL)** register (see page 1103), the timer begins counting up from 0x0 or down from its preloaded value. Alternatively, if the TnWOT bit is set in the **GPTMTnMR** register, once the TnEN bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger Mode” on page 1086). Table 16-4 on page 1077 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 16-4. Counter Values When the Timer is Enabled in Periodic or One-Shot Modes**

| Register        | Count Down Mode                                                                                                | Count Up Mode                                              |
|-----------------|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| <b>GPTMTnR</b>  | <b>GPTMTnILR</b>                                                                                               | 0x0                                                        |
| <b>GPTMTnV</b>  | <b>GPTMTnILR</b> in concatenated mode; <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> in individual mode | 0x0                                                        |
| <b>GPTMTnPS</b> | <b>GPTMTnPR</b> in individual mode; not available in concatenated mode                                         | 0x0 in individual mode; not available in concatenated mode |

When the timer is counting down and it reaches the timeout event (0x0), the timer reloads its start value from the **GPTMTnILR** and the **GPTMTnPR** registers on the next cycle. When the timer is counting up and it reaches the timeout event (the value in the **GPTMTnILR** and the optional

**GPTMTnPR** registers), the timer reloads with 0x0. If configured to be a one-shot timer, the timer stops counting and clears the TnEN bit in the **GPTMCTL** register. If configured as a periodic timer, the timer starts counting again on the next cycle.

In periodic, snap-shot mode (TnMR field is 0x2 and the TnSNAPS bit is set in the **GPTMTnMR** register), the value of the timer at the time-out event is loaded into the **GPTMTnR** register and the value of the prescaler is loaded into the **GPTMTnPS** register. The free-running counter value is shown in the **GPTMTnV** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry by examining the snapshot values and the current value of the free-running timer. Snapshot mode is not available when the timer is configured in one-shot mode.

In addition to reloading the count value, the GPTM can generate interrupts, CCP outputs and triggers when it reaches the time-out event. The GPTM sets the TnTORIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 1113), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 1119). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register (see page 1110), the GPTM also sets the TnTOMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 1116). The time-out interrupt can be disabled entirely by setting the TACINTD bit in the **GPTM Timer n Mode (GPTMTnMR)** register. In this case, the TnTORIS bit does not even set in the **GPTMRIS** register.

By setting the TnMIE bit in the **GPTMTnMR** register, an interrupt condition can also be generated when the Timer value equals the value loaded into the **GPTM Timer n Match (GPTMTnMATCHR)** and **GPTM Timer n Prescale Match (GPTMTnPMR)** registers. This interrupt has the same status, masking, and clearing functions as the time-out interrupt, but uses the match interrupt bits instead (for example, the raw interrupt status is monitored via TnMRIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register). Note that the interrupt status bits are not updated by the hardware unless the TnMIE bit in the **GPTMTnMR** register is set, which is different than the behavior for the time-out interrupt. The ADC trigger is enabled by setting the TnOTE bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 682.

The TCACT field of the **GPTM Timer n Mode (GPTMTnMR)** register can be configured to clear, set or toggle an output on a time-out event.

If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting down, the counter loads the new value on the next clock cycle and continues counting from the new value if the TnILD bit in the **GPTMTnMR** register is clear. If the TnILD bit is set, the counter loads the new value after the next timeout. If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting up, the timeout event is changed on the next cycle to the new value. If software updates the **GPTM Timer n Value (GPTMTnV)** register while the counter is counting up or down, the counter loads the new value on the next clock cycle and continues counting from the new value. If software updates the **GPTMTnMATCHR** or the **GPTMTnPMR** registers, the new values are reflected on the next clock cycle if the TnMRSU bit in the **GPTMTnMR** register is clear. If the TnMRSU bit is set, the new value will not take effect until the next timeout.

If the TnSTALL bit in the **GPTMCTL** register is set and the RTCEN bit is not set in the **GPTMCTL** register, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution. If the RTCEN bit is set, it prevents the TnSTALL bit from freezing the count when the processor is halted by the debugger.

The following table shows a variety of configurations for a 16-bit free-running timer while using the prescaler. All values assume a 120-MHz clock with  $T_c$ =Pending ns (clock period). The prescaler can only be used when a 16/32-bit timer is configured in 16-bit mode.

**Table 16-5. 16-Bit Timer With Prescaler Configurations**

| Prescale (8-bit value) | # of Timer Clocks (Tc) <sup>a</sup> | Max Time | Units |
|------------------------|-------------------------------------|----------|-------|
| 00000000               | 1                                   | Pending  | ms    |
| 00000001               | 2                                   | Pending  | ms    |
| 00000010               | 3                                   | Pending  | ms    |
| -----                  | --                                  | --       | --    |
| 11111101               | 254                                 | Pending  | ms    |
| 11111110               | 255                                 | Pending  | ms    |
| 11111111               | 256                                 | Pending  | ms    |

a. Tc is the clock period.

### **Timer Compare Action Mode**

The timer compare mode is an extension to the GPTM's existing one-shot and periodic modes. This mode can be used when an application requires a pin change state at some time in the future, regardless of the processor state. The compare mode does not operate when the PWM mode is active and is mutually exclusive to the PWM mode. The compare mode is enabled when the TAMR field is set to 0x1 or 0x2 (one-shot or periodic), the TnAMS bit is 0 (capture or compare mode) and the TCACT field is nonzero in the **GPTM Timer n Mode (GPTMTnMR)** register. Depending on the TCACT encoding, the timer can perform a set, clear or toggle on the corresponding CCPn pin when a timer match occurs. In 16-bit mode, the corresponding CCP pin can have an action applied, but when operating in 32-bit mode, the action can only be applied to the even CCP pin.

The TCACT field can be changed while the GPTM is enabled to generate different combinations of actions. For example, during a periodic event, encodings TCACT = 0x6 or 0x7 can be used to force the initial state of the CCPn pin before the first interrupt and following that, TCACT=0x2 and TCACT=0x3 can be used (alternately) to change the sense of the pin for the subsequent toggle, while possible changing load value for the next period.

The time-out interrupts used for one-shot and periodic modes are used in the compare action modes. Thus, the TnTORIS bits in the **GPTMRIS** register are triggered if the appropriate mask bits are set in the **GPTMIM** register.

### **16.3.3.2 Real-Time Clock Timer Mode**

In Real-Time Clock (RTC) mode, the concatenated versions of the Timer A and Timer B registers are configured as an up-counter. When RTC mode is selected for the first time after reset, the counter is loaded with a value of 0x1. All subsequent load values must be written to the **GPTM Timer n Interval Load (GPTMTnILR)** registers (see page 1121). If the **GPTMTnILR** register is loaded with a new value, the counter begins counting at that value and rolls over at the fixed value of 0xFFFFFFFF. Table 16-6 on page 1079 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 16-6. Counter Values When the Timer is Enabled in RTC Mode**

| Register | Count Down Mode | Count Up Mode |
|----------|-----------------|---------------|
| GPTMTnR  | Not available   | 0x1           |
| GPTMTnV  | Not available   | 0x1           |
| GPTMTnPS | Not available   | Not available |

The input clock on a CCP0 input is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1-Hz rate and is passed along to the input of the counter.

When software writes the TAEN bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x1. When the current count value matches the preloaded value in the **GPTMTnMATCHR** registers, the GPTM asserts the RTCRIS bit in **GPTMRIS** and continues counting until either a hardware reset, or it is disabled by software (clearing the TAEN bit). When the timer value reaches the terminal count, the timer rolls over and continues counting up from 0x0. If the RTC interrupt is enabled in **GPTMIMR**, the GPTM also sets the RTCMIS bit in **GPTMMIS** and generates a controller interrupt. The status flags are cleared by writing the RTCCINT bit in **GPTMICR**.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

In addition to generating interrupts, the RTC can generate a  $\mu$ DMA trigger. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 682.

### 16.3.3.3 Input Edge-Count Mode

**Note:** For rising-edge detection, the input signal must be High for at least two clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low for at least two clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the frequency.

In Edge-Count mode, the timer is configured as a 24-bit up- or down-counter including the optional prescaler with the upper count value stored in the **GPTM Timer n Prescale (GPTMTnPR)** register and the lower bits in the **GPTMTnR** register. In this mode, the timer is capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge-Count mode, the TnCMR bit of the **GPTMTnMR** register must be cleared. The type of edge that the timer counts is determined by the TnEVENT fields of the **GPTMCTL** register. During initialization in down-count mode, the **GPTMTnMATCHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted. In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Note that when executing an up-count, that the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**. Table 16-7 on page 1080 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 16-7. Counter Values When the Timer is Enabled in Input Edge-Count Mode**

| Register       | Count Down Mode                                      | Count Up Mode |
|----------------|------------------------------------------------------|---------------|
| <b>GPTMTnR</b> | <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> | 0x0           |
| <b>GPTMTnV</b> | <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> | 0x0           |

When software writes the TnEN bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements or increments the counter by 1 until the event count matches **GPTMTnMATCHR** and **GPTMTnPMR**. When the counts match, the GPTM asserts the CnMRIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode match interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the CnMMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In up-count mode, the current count of the input events is held in both the **GPTMTnR** and **GPTMTnV** registers. In down-count mode, the current count of the input events can be obtained by subtracting the **GPTMTnR** or **GPTMTnV** from the value made up of the **GPTMTnPR** and **GPTMTnILR** register combination.

In addition to generating interrupts, an ADC and/or a  $\mu$ DMA trigger can be generated. The ADC trigger is enabled by setting the Tn0TE bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The  $\mu$ DMA trigger is enabled by

configuring and enabling the appropriate  $\mu$ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 682.

After the match value is reached in down-count mode, the counter is then reloaded using the value in **GPTMTnILR** and **GPTMTnPR** registers, and stopped because the GPTM automatically clears the TnEN bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until TnEN is re-enabled by software. In up-count mode, the timer is reloaded with 0x0 and continues counting.

Figure 16-2 on page 1081 shows how Input Edge-Count mode works. In this case, the timer start value is set to **GPTMTnILR** = 0x000A and the match value is set to **GPTMTnMATCHR** = 0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted because the timer automatically clears the TnEN bit after the current count matches the value in the **GPTMTnMATCHR** register.

**Figure 16-2. Input Edge-Count Mode Example, Counting Down**

#### 16.3.3.4 Input Edge-Time Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Time mode, the timer is configured as a 24-bit up- or down-counter including the optional prescaler with the upper timer value stored in the **GPTMTnPR** register and the lower bits in the **GPTMTnILR** register. In this mode, the timer is initialized to the value loaded in the **GPTMTnILR** and **GPTMTnPR** registers when counting down and 0x0 when counting up. The timer is capable of capturing three types of events: rising edge, falling edge, or both. The timer is placed into Edge-Time mode by setting the TnCMR bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the TnEVENT fields of the **GPTMCTL** register. Table 16-8 on page 1082 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 16-8. Counter Values When the Timer is Enabled in Input Event-Count Mode**

| Register | Count Down Mode | Count Up Mode |
|----------|-----------------|---------------|
| TnR      | GPTMTnILR       | 0x0           |
| TnV      | GPTMTnILR       | 0x0           |

When software writes the TnEN bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current timer counter value is captured in the **GPTMTnR** and **GPTMTnPS** register and is available to be read by the microcontroller. The GPTM then asserts the CnERIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the CnEMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In this mode, the **GPTMTnR** and **GPTMTnPS** registers hold the time at which the selected input event occurred while the **GPTMTnV** register holds the free-running timer value. These registers can be read to determine the time that elapsed between the interrupt assertion and the entry into the ISR.

In addition to generating interrupts, an ADC and/or a  $\mu$ DMA trigger can be generated. The ADC trigger is enabled by setting the TnOTE bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The  $\mu$ DMA trigger is enabled by configuring the appropriate  $\mu$ DMA channel as well as the type of trigger selected in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 682.

After an event has been captured, the timer does not stop counting. It continues to count until the TnEN bit is cleared. When the timer reaches the timeout value, it is reloaded with 0x0 in up-count mode and the value from the **GPTMTnILR** and **GPTMTnPR** registers in down-count mode.

Figure 16-3 on page 1083 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers, and is held there until another rising edge is detected (at which point the new count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers).

**Figure 16-3. 16-Bit Input Edge-Time Mode Example**

**Note:** When operating in Edge-time mode, the counter uses a modulo  $2^{24}$  count if prescaler is enabled or  $2^{16}$ , if not. If there is a possibility the edge could take longer than the count, then another timer configured in periodic-timer mode can be implemented to ensure detection of the missed edge. The periodic timer should be configured in such a way that:

- The periodic timer cycles at the same rate as the edge-time timer
- The periodic timer interrupt has a higher interrupt priority than the edge-time timeout interrupt.
- If the periodic timer interrupt service routine is entered, software must check if an edge-time interrupt is pending and if it is, the value of the counter must be subtracted by 1 before being used to calculate the snapshot time of the event.

### 16.3.3.5 PWM Mode

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a 24-bit down-counter with a start value (and thus period) defined by the **GPTMTnILR** and **GPTMTnPR** registers. In this mode, the PWM frequency and period are synchronous events and therefore guaranteed to be glitch free. PWM mode is enabled with the **GPTMTnMR** register by setting the TnAMS bit to 0x1, the TnCMR bit to 0x0, and the TnMR field to 0x2. Table 16-9 on page 1083 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 16-9. Counter Values When the Timer is Enabled in PWM Mode**

| Register       | Count Down Mode  | Count Up Mode |
|----------------|------------------|---------------|
| <b>GPTMTnR</b> | <b>GPTMTnILR</b> | Not available |
| <b>GPTMTnV</b> | <b>GPTMTnILR</b> | Not available |

When software writes the TnEN bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0 state. Alternatively, if the TnWOT bit is set in the **GPTMTnMR** register, once the TnEN bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger

Mode” on page 1086). On the next counter cycle in periodic mode, the counter reloads its start value from the **GPTMTnILR** and **GPTMTnPR** registers and continues counting until disabled by software clearing the TnEN bit in the **GPTMCTL** register. The timer is capable of generating interrupts based on three types of events: rising edge, falling edge, or both. The event is configured by the TnEVENT field of the **GPTMCTL** register, and the interrupt is enabled by setting the TnPWMIE bit in the **GPTMTnMR** register. When the event occurs, the CnERIS bit is set in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the CnEMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. Note that the interrupt status bits are not updated unless the TnPWMIE bit is set.

In addition, when the TnPWMIE bit is set and a capture event occurs, the Timer automatically generates triggers to the ADC and DMA if the trigger capability is enabled by setting the Tn0TE bit in the **GPTMCTL** register and the CnEDMAEN bit in the **GPTMDMAEV** register, respectively.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** and **GPTMTnPR** registers (its start state), and is deasserted when the counter value equals the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Software has the capability of inverting the output PWM signal by setting the TnPWML bit in the **GPTMCTL** register.

**Note:** If PWM output inversion is enabled, edge detection interrupt behavior is reversed. Thus, if a positive-edge interrupt trigger has been set and the PWM inversion generates a positive edge, no event-trigger interrupt asserts. Instead, the interrupt is generated on the negative edge of the PWM signal.

Figure 16-4 on page 1085 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and **TnPWML** = 0 (duty cycle would be 33% for the **TnPWML** = 1 configuration). For this example, the start value is **GPTMTnILR**=0xC350 and the match value is **GPTMTnMATCHR**=0x411A.

**Figure 16-4. 16-Bit PWM Mode Example**

When synchronizing the timers using the **GPTMSYNC** register, the timer must be properly configured to avoid glitches on the CCP outputs. Both the TnPLO and the TnMRSU bits must be set in the **GPTMTnMR** register. Figure 16-5 on page 1085 shows how the CCP output operates when the TnPLO and TnMRSU bits are set and the **GPTMTnMATCHHR** value is greater than the **GPTMTnILR** value.

**Figure 16-5. CCP Output, GPTMTnMATCHHR > GPTMTnILR**

Figure 16-6 on page 1086 shows how the CCP output operates when the PLO and MRSU bits are set and the **GPTMTnMATCHHR** value is the same as the **GPTMTnILR** value. In this situation, if the **PLO** bit is 0, the CCP signal goes high when the **GPTMTnILR** value is loaded and the match would be essentially ignored.

**Figure 16-6. CCP Output,  $GPTMTnMATCHR = GPTMTnILR$** 

Figure 16-7 on page 1086 shows how the CCP output operates when the PLO and MRSU bits are set and the **GPTMTnILR** is greater than the **GPTMTnMATCHR** value.

**Figure 16-7. CCP Output,  $GPTMTnILR > GPTMTnMATCHR$** 

### 16.3.4 Wait-for-Trigger Mode

The Wait-for-Trigger mode allows daisy chaining of the timer modules such that once configured, a single timer can initiate multiple timing events using the Timer triggers. Wait-for-Trigger mode is enabled by setting the TnWOT bit in the **GPTMTnMR** register. When the TnWOT bit is set, Timer N+1 does not begin counting until the timer in the previous position in the daisy chain (Timer N) reaches its time-out event. The daisy chain is configured such that GPTM1 always follows GPTM0, GPTM2 follows GPTM1, and so on. If Timer A is configured as a 32-bit (16/32-bit mode) timer (controlled by the GPTMCFG field in the **GPTMCFG** register), it triggers Timer A in the next module. If Timer A is configured as a 16-bit (16/32-bit mode) timer, it triggers Timer B in the same module, and Timer B triggers Timer A in the next module. Figure 16-8 on page 1087 shows how the GPTMCFG bit affects the daisy chain. This function is valid for one-shot, periodic, and PWM modes.

**Note:** If the application requires cyclical daisy-chaining, the TAWOT bit in the **GPTMTAMR** register of Timer 0 can be set. In this case, Timer 0 waits for a trigger from the last timer module in the chain.

Figure 16-8. Timer Daisy Chain

### 16.3.5 Synchronizing GP Timer Blocks

The **GPTM Synchronizer Control (GPTMSYNC)** register in the GPTM0 block can be used to synchronize selected timers to begin counting at the same time. Setting a bit in the **GPTMSYNC** register causes the associated timer to perform the actions of a timeout event. An interrupt is not generated when the timers are synchronized. If a timer is being used in concatenated mode, only the bit for Timer A must be set in the **GPTMSYNC** register.

**Note:** All timers must use the same clock source for this feature to work correctly.

Table 16-10 on page 1087 shows the actions for the timeout event performed when the timers are synchronized in the various timer modes.

**Table 16-10. Timeout Actions for GPTM Modes**

| Mode                                           | Count Dir | Time Out Action   |
|------------------------------------------------|-----------|-------------------|
| 32-bit One-Shot<br>(concatenated timers)       | —         | N/A               |
| 32-bit Periodic<br>(concatenated timers)       | Down      | Count value = ILR |
|                                                | Up        | Count value = 0   |
| 32-bit RTC<br>(concatenated timers)            | Up        | Count value = 0   |
| 16-bit One Shot<br>(individual/split timers)   | —         | N/A               |
| 16-bit Periodic<br>(individual/split timers)   | Down      | Count value = ILR |
|                                                | Up        | Count value = 0   |
| 16-bit Edge-Count<br>(individual/split timers) | Down      | Count value = ILR |
|                                                | Up        | Count value = 0   |
| 16-bit Edge-Time<br>(individual/split timers)  | Down      | Count value = ILR |
|                                                | Up        | Count value = 0   |
| 16-bit PWM                                     | Down      | Count value = ILR |

### 16.3.6 DMA Operation

The timers each have a dedicated  $\mu$ DMA channel and can provide a request signal to the  $\mu$ DMA controller. Pulse requests are generated by a timer via its own `dma_req` signal. A `dma_done` signal is provided from the  $\mu$ DMA to each timer to indicate transfer completion and trigger a  $\mu$ DMA done interrupt (DMA<sub>NRIS</sub>) in the **GPTM Raw Interrupt Status Register (GPTMRIS) register**. The request is a burst type and occurs whenever a timer raw interrupt condition occurs. The arbitration size of the  $\mu$ DMA transfer should be set to the amount of data that should be transferred whenever a timer event occurs.

For example, to transfer 256 items, 8 items at a time every 10 ms, configure a timer to generate a periodic timeout at 10 ms. Configure the  $\mu$ DMA transfer for a total of 256 items, with a burst size of 8 items. Each time the timer times out, the  $\mu$ DMA controller transfers 8 items, until all 256 items have been transferred. Refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 677 for more details about programming the  $\mu$ DMA controller.

A **GPTM DMA Event (GPTMDMAEV) register** is provided to enable the types of events that can cause a `dma_req` signal assertion by the timer module. Application software can enable a `dma_req` trigger for a match, capture or time-out event for each timer using the **GPTMDMAEV** register. For an individual timer, all active timer trigger events that have been enabled through the **GPTMDMAEV** register are ORed together to create a single `dma_req` pulse that is sent to the  $\mu$ DMA. When the  $\mu$ DMA transfer has completed, a `dma_done` signal is sent to the timer resulting in a DMA<sub>NRIS</sub> bit set in the **GPTMRIS** register.

### 16.3.7 ADC Operation

The timer has the capability to trigger the ADC when the TnOTE bit is set in the **GPTMCTL** register at offset 0x00C. The **GPTM ADC Event (GPTMADCEV) register** is additionally provided so that the type of ADC trigger can be defined. For example, by setting the CBMADCEN bit in the **GPTMADCEV** register, a trigger pulse will be sent to the ADC whenever a Capture Match event occurs in GPTM B. Similar to the  $\mu$ DMA operation, all active trigger events that have also been enabled in the **GPTMADCEV** register are ORed together to create an ADC trigger pulse.

### 16.3.8 Accessing Concatenated 16/32-Bit GPTM Register Values

The GPTM is placed into concatenated mode by writing a 0x0 or a 0x1 to the GPTMCFG bit field in the **GPTM Configuration (GPTMCFG) register**. In both configurations, certain 16/32-bit GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM Timer A Interval Load (GPTMTAILR) register** [15:0], see page 1121
- **GPTM Timer B Interval Load (GPTMTBILR) register** [15:0], see page 1122
- **GPTM Timer A (GPTMTAR) register** [15:0], see page 1129
- **GPTM Timer B (GPTMTBR) register** [15:0], see page 1130
- **GPTM Timer A Value (GPTMTAV) register** [15:0], see page 1131
- **GPTM Timer B Value (GPTMTBV) register** [15:0], see page 1132
- **GPTM Timer A Match (GPTMTAMATCHR) register** [15:0], see page 1123
- **GPTM Timer B Match (GPTMTBMATCHR) register** [15:0], see page 1124

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

**GPTMTBILR[15:0] : GPTMTAILR[15:0]**

Likewise, a 32-bit read access to **GPTMTAR** returns the value:

**GPTMTBILR[15:0] : GPTMTAR[15:0]**

A 32-bit read access to **GPTMTAV** returns the value:

**GPTMTBILR[15:0] : GPTMTAV[15:0]**

## 16.4 Initialization and Configuration

To use a GPTM, the appropriate **TIMERN** bit must be set in the **RCGCTIMER** register (see page 384). If using any CCP pins, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (see page 386). To find out which GPIO port to enable, refer to Table 29-4 on page 1873. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the CCP signals to the appropriate pins (see page 788 and Table 29-5 on page 1887).

This section shows module initialization and configuration examples for each of the supported timer modes.

### 16.4.1 One-Shot/Periodic Timer Mode

The GPTM is configured for One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the **TnEN** bit in the **GPTMCTL** register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0000.
3. Configure the **TnMR** field in the **GPTM Timer n Mode Register (GPTMTnMR)**:
  - a. Write a value of 0x1 for One-Shot mode.
  - b. Write a value of 0x2 for Periodic mode.
4. Optionally configure the **TnSNAPS**, **TnWOT**, **TnMTE**, and **TnCDIR** bits in the **GPTMTnMR** register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down. In addition, if using CCP pins, the **TnACT** field can be programmed to configure the compare action.
5. Load the start value into the **GPTM Timer n Interval Load Register (GPTMTnILR)**.
6. If interrupts are required, set the appropriate bits in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the **TnEN** bit in the **GPTMCTL** register to enable the timer and start counting.
8. Poll the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

If the TnMIE bit in the **GPTMTnMR** register is set, the RTCRIS bit in the **GPTMRIS** register is set, and the timer continues counting. In One-Shot mode, the timer stops counting after the time-out event. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode reloads the timer and continues counting after the time-out event.

### 16.4.2 Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on an even CCP input. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the TAEN bit is cleared) before making any changes.
2. If the timer has been operating in a different mode prior to this, clear any residual set bits in the **GPTM Timer n Mode (GPTMTnMR)** register before reconfiguring.
3. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0001.
4. Write the match value to the **GPTM Timer n Match Register (GPTMTnMATCHR)**.
5. Set/clear the RTCEN and TnSTALL bit in the **GPTM Control Register (GPTMCTL)** as needed.
6. If interrupts are required, set the RTCIM bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the TAEN bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTnMATCHR** register, the GPTM asserts the RTCRIS bit in the **GPTMRIS** register and continues counting until Timer A is disabled or a hardware reset. The interrupt is cleared by writing the RTCCINT bit in the **GPTMICR** register. Note that if the **GPTMTnILR** register is loaded with a new value, the timer begins counting at this new value and continues until it reaches 0xFFFF.FFFF, at which point it rolls over.

### 16.4.3 Input Edge-Count Mode

A timer is configured to Input Edge-Count mode by the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the TnCMR field to 0x0 and the TnMR field to 0x3.
4. Configure the type of event(s) that the timer captures by writing the TnEVENT field of the **GPTM Control (GPTMCTL)** register.
5. Program registers according to count direction:
  - In down-count mode, the **GPTMTnMATCHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted.
  - In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Note that when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

6. If interrupts are required, set the CnMIM bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
7. Set the TnEN bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
8. Poll the CnMRIS bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the CnMCINT bit of the **GPTM Interrupt Clear (GPTMICR)** register.

When counting down in Input Edge-Count Mode, the timer stops after the programmed number of edge events has been detected. To re-enable the timer, ensure that the TnEN bit is cleared and repeat Step #4 on page 1090 through #9 on page 1091.

#### 16.4.4 Input Edge Time Mode

A timer is configured to Input Edge Time mode by the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the TnCMR field to 0x1 and the TnMR field to 0x3 and select a count direction by programming the TnCDIR bit.
4. Configure the type of event that the timer captures by writing the TnEVENT field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. If interrupts are required, set the CnEIM bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the TnEN bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
9. Poll the CnERIS bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the CnECINT bit of the **GPTM Interrupt Clear (GPTMICR)** register. The time at which the event happened can be obtained by reading the **GPTM Timer n (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register and clearing the TnILD bit in the **GPTMTnMR** register. The change takes effect at the next cycle after the write.

#### 16.4.5 PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the TnAMS bit to 0x1, the TnCMR bit to 0x0, and the TnMR field to 0x2.

4. Configure the output state of the PWM signal (whether or not it is inverted) in the TnPWML field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. If PWM interrupts are used, configure the interrupt condition in the TnEVENT field in the **GPTMCTL** register and enable the interrupts by setting the TnPWMIE bit in the **GPTMTnMR** register. Note that edge detect interrupt behavior is reversed when the PWM output is inverted (see page 1103).
7. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
8. Load the **GPTM Timer n Match (GPTMTnMATCHR)** register with the match value.
9. Set the TnEN bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Time mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

## 16.5 Register Map

Table 16-11 on page 1092 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- 16/32-bit Timer 0: 0x4003.0000
- 16/32-bit Timer 1: 0x4003.1000
- 16/32-bit Timer 2: 0x4003.2000
- 16/32-bit Timer 3: 0x4003.3000
- 16/32-bit Timer 4: 0x4003.4000
- 16/32-bit Timer 5: 0x4003.5000
- 16/32-bit Timer 6: 0x400E.0000
- 16/32-bit Timer 7: 0x400E.1000

Note that the GP Timer module clock must be enabled before the registers can be programmed (see page 384). There must be a delay of 3 system clocks after the Timer module clock is enabled before any Timer module registers are accessed.

**Table 16-11. Timers Register Map**

| Offset | Name     | Type | Reset       | Description         | See page |
|--------|----------|------|-------------|---------------------|----------|
| 0x000  | GPTMCFG  | RW   | 0x0000.0000 | GPTM Configuration  | 1094     |
| 0x004  | GPTMTAMR | RW   | 0x0000.0000 | GPTM Timer A Mode   | 1095     |
| 0x008  | GPTMTBMR | RW   | 0x0000.0000 | GPTM Timer B Mode   | 1099     |
| 0x00C  | GPTMCTL  | RW   | 0x0000.0000 | GPTM Control        | 1103     |
| 0x010  | GPTMSYNC | RW   | 0x0000.0000 | GPTM Synchronize    | 1107     |
| 0x018  | GPTMIMR  | RW   | 0x0000.0000 | GPTM Interrupt Mask | 1110     |

**Table 16-11. Timers Register Map (continued)**

| Offset | Name         | Type | Reset       | Description                    | See page |
|--------|--------------|------|-------------|--------------------------------|----------|
| 0x01C  | GPTMRIS      | RO   | 0x0000.0000 | GPTM Raw Interrupt Status      | 1113     |
| 0x020  | GPTMMIS      | RO   | 0x0000.0000 | GPTM Masked Interrupt Status   | 1116     |
| 0x024  | GPTMICR      | W1C  | 0x0000.0000 | GPTM Interrupt Clear           | 1119     |

## 16.6 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

**Register 1: GPTM Configuration (GPTMCFG), offset 0x000**

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

**Important:** Bits in this register should only be changed when the TAEN and TBEN bits in the **GPTMCTL** register are cleared.

**GPTM Configuration (GPTMCFG)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x000  
 Type RW, reset 0x0000.0000

**Register 2: GPTM Timer A Mode (GPTMTAMR), offset 0x004**

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the TAAMS bit, clear the TACMR bit, and configure the TAMR field to 0x1 or 0x2.

This register controls the modes for Timer A when it is used individually. When Timer A and Timer B are concatenated, this register controls the modes for both Timer A and Timer B, and the contents of **GPTMTBMR** are ignored.

**Important:** Except for the TCACT bit field, all other bits in this register should only be changed when the TAEN bit in the **GPTMCTL** register is cleared.

**GPTM Timer A Mode (GPTMTAMR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000

**Register 3: GPTM Timer B Mode (GPTMTBMR), offset 0x008**

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the TBAMS bit, clear the TBCMR bit, and configure the TBMR field to 0x1 or 0x2.

This register controls the modes for Timer B when it is used individually. When Timer A and Timer B are concatenated, this register is ignored and **GPTMTAMR** controls the modes for both Timer A and Timer B.

**Important:** Except for the TCACT bit field, all other bits in this register should only be changed when the TBEN bit in the **GPTMCTL** register is cleared.

**GPTM Timer B Mode (GPTMTBMR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000

## Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

**Important:** Bits in this register should only be changed when the TnEN bit for the respective timer is cleared.

### GPTM Control (GPTMCTL)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

16/32-bit Timer 2 base: 0x4003.2000

16/32-bit Timer 3 base: 0x4003.3000

16/32-bit Timer 4 base: 0x4003.4000

16/32-bit Timer 5 base: 0x4003.5000

16/32-bit Timer 6 base: 0x400E.0000

16/32-bit Timer 7 base: 0x400E.1000

Offset 0x00C

Type RW, reset 0x0000.0000

**Register 6: GPTM Interrupt Mask (GPTMIMR), offset 0x018**

This register allows software to enable/disable GPTM controller-level interrupts. Setting a bit enables the corresponding interrupt, while clearing a bit disables it.

**GPTM Interrupt Mask (GPTMIMR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000

**Register 7: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C**

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMIMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

**Note:** The state of the **GPTMRIS** register is not affected by disabling and then re-enabling the timer using the TnEN bits in the **GPTM Control (GPTMCTL)** register. If an application requires that all or certain status bits should not carry over after re-enabling the timer, then the appropriate bits in the **GPTMRIS** register should be cleared using the **GPTMICR** register prior to re-enabling the timer. If this is not done, any status bits set in the **GPTMRIS** register and unmasked in the **GPTMIMR** register generate an interrupt once the timer is re-enabled.

**GPTM Raw Interrupt Status (GPTMRIS)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000

## Register 8: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register shows the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

### GPTM Masked Interrupt Status (GPTMMIS)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x020

## Register 9: GPTM Interrupt Clear (GPTMICR), offset 0x024

This register is used to clear the status bits in the **GPTMRIS** and **GPTMMIS** registers. Writing a 1 to a bit clears the corresponding bit in the **GPTMRIS** and **GPTMMIS** registers.

### GPTM Interrupt Clear (GPTMICR)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x024

**Register 10: GPTM Timer A Interval Load (GPTMTAILR), offset 0x028**

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Interval Load (GPTMTBILR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

**Register 11: GPTM Timer B Interval Load (GPTMTBILR), offset 0x02C**

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAILR** register. Reads from this register return the current value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the load value. Bits 31:16 are reserved in both cases.

**Register 12: GPTM Timer A Match (GPTMTAMATCHR), offset 0x030**

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTAILR**, determines the duty cycle of the output PWM signal.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAMATCHR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Match (GPTMTBMATCHR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBMATCHR**.

**Register 13: GPTM Timer B Match (GPTMTBMATCHR), offset 0x034**

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTBILR** determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTBILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTBILR**, determines the duty cycle of the output PWM signal.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAMATCHR** register. Reads from this register return the current match value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the match value. Bits 31:16 are reserved in both cases.

**Register 14: GPTM Timer A Prescale (GPTMTAPR), offset 0x038**

This register allows software to extend the range of the timers when they are used individually. When in one-shot or periodic down count modes, this register acts as a true prescaler for the timer counter. When acting as a true prescaler, the prescaler counts down to 0 before the value in the **GPTMTAR** and **GPTMTAV** registers are incremented. In all other individual/split modes, this register is a linear extension of the upper range of the timer counter, holding bits 23:16 in the 16-bit modes of the 16/32-bit GPTM.

**Register 18: GPTM Timer A (GPTMTAR), offset 0x048**

This register shows the current value of the Timer A counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B (GPTMTBR)** register). In the 16-bit Input Edge Count, Input Edge Time, and PWM modes, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTAV** register. To read the value of the prescaler in periodic snapshot mode, read the **Timer A Prescale Snapshot (GPTMTAPS)** register.

**GPTM Timer A (GPTMTAR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000

|-----------|------|------|-------------|-----------------------|
| 31:0      | TAR  | RO   | 0xFFFF.FFFF | GPTM Timer A Register |

A read returns the current value of the **GPTM Timer A Count Register**, in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Register 19: GPTM Timer B (GPTMTBR), offset 0x04C**

This register shows the current value of the Timer B counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAR** register. Reads from this register return the current value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler in Input Edge Count, Input Edge Time, and PWM modes, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTBV** register. To read the value of the prescaler in periodic snapshot mode, read the **Timer B Prescale Snapshot (GPTMTBPS)** register.

**GPTM Timer B (GPTMTBR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000

 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x04C  
 Type RO, reset 0x0000.FFFF

| Bit/Field | Name | Type | Reset       | Description           |
|-----------|------|------|-------------|-----------------------|
| 31:0      | TBR  | RO   | 0x0000.FFFF | GPTM Timer B Register |

A read returns the current value of the **GPTM Timer B Count Register**, in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Register 20: GPTM Timer A Value (GPTMTAV), offset 0x050**

When read, this register shows the current, free-running value of Timer A in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry when using the snapshot feature with the periodic operating mode. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAV** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Value (GPTMTBV)** register). In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

**GPTM Timer A Value (GPTMTAV)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x050  
 Type RW, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset       | Description        |
|-----------|------|------|-------------|--------------------|
| 31:0      | TAV  | RW   | 0xFFFF.FFFF | GPTM Timer A Value |

A read returns the current, free-running value of Timer A in all modes. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

**Note:** In 16-bit mode, only the lower 16-bits of the **GPTMTAV** register can be written with a new value. Writes to the prescaler bits have no effect.

**Register 21: GPTM Timer B Value (GPTMTBV), offset 0x054**

When read, this register shows the current, free-running value of Timer B in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry. When written, the value written into this register is loaded into the **GPTMTBR** register on the next clock cycle.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAV** register. Reads from this register return the current free-running value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

**GPTM Timer B Value (GPTMTBV)**

|           |      |      |       | 0 Timer A and Timer B counters are 16 bits each with an 8-bit prescale counter. |
|           |      |      |       | 1 Timer A and Timer B counters are 32 bits each with a 16-bit prescale counter. |

**Register 28: GPTM Clock Configuration (GPTMCC), offset 0xFC8**

The **GPTMCC** register controls the clock source for the General-Purpose Timer module.

**Note:** When the ALTCLK bit is set in the **GPTMCC** register to enable using the alternate clock source, the synchronization imposes restrictions on the starting count value (down-count), terminal value (up-count) and the match value. This restriction applies to all modes of operation. Each event must be spaced by 4 Timer (ALTCLK) clock periods + 2 system clock periods. If some events do not meet this requirement, then it is possible that the timer block may need to be reset for correct functionality to be restored.

Example:  $ALTCLK = T_{PIOSC} = 62.5ns$  (16Mhz Trimmed)

$T_{hclk} = 1\mu s$  (1Mhz)

$4 * 62.5ns + 2 * 1\mu s = 2.25\mu s$   $2.25\mu s / 62.5ns = 36$  or 0x23

The minimum values for the periodic or one-shot with a match interrupt enabled are:  
**GPTMTAMATCHR = 0x23 GPTMTAILR = 0x46**

## 17 Watchdog Timers

A watchdog timer can generate a non-maskable interrupt (NMI), a regular interrupt or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way. The TM4C129DNCZAD microcontroller has two Watchdog Timer Modules, one module is clocked by the system clock (Watchdog Timer 0) and the other (Watchdog Timer 1) is clocked by the clock source programmed in the ALTCLK field of the **Alternate Clock Configuration (ALTCLKCFG)** register, System Control offset 0x138. The two modules are identical except that WDT1 is in a different clock domain, and therefore requires synchronizers. As a result, WDT1 has a bit defined in the **Watchdog Timer Control (WDTCTL)** register to indicate when a write to a WDT1 register is complete. Software can use this bit to ensure that the previous access has completed before starting the next access.

The TM4C129DNCZAD controller has two Watchdog Timer modules with the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

## 17.1 Block Diagram

Figure 17-1. WDT Module Block Diagram

## 17.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. The watchdog interrupt can be programmed to be a non-maskable interrupt (NMI) using the **INTTYPE** bit in the **WDTCTL** register. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled by setting the **RESEN** bit in the **WDTCTL** register, the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

The watchdog timer is disabled by default out of reset. To achieve maximum watchdog protection of the device, the watchdog timer can be enabled at the start of the reset vector.

### 17.2.1 Register Access Timing

Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The WRC bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for WRC=1 prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock.

## 17.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the Rn bit in the **Watchdog Timer Run Mode Clock Gating Control (RCGCWD)** register, see page 383.

The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If WDT1, wait for the WRC bit in the **WDTCTL** register to be set.
3. Set the INTEN bit (if interrupts are required) or the RESEN bit (if a reset is required after two timeouts) in the **WDTCTL** register. The Watchdog Timer starts when either of them is enabled.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

To service the watchdog, periodically reload the count value into the **WDTLOAD** register to restart the count. The interrupt can be enabled using the INTEN bit in the **WDTCTL** register to allow the processor to attempt corrective action if the watchdog is not serviced often enough. The RESEN bit in **WDTCTL** can be set so that the system resets if the failure is not recoverable using the ISR.

**Note:** The application should be sure not to modify the ALTCLK encoding in the **ALTCLKCFG** register while the WDT1 is enabled and running.

## 17.4 Register Map

Table 17-1 on page 1148 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address:

- WDT0: 0x4000.0000
- WDT1: 0x4000.1000

Note that the Watchdog Timer module clock must be enabled before the registers can be programmed (see page 383).

**Table 17-1. Watchdog Timers Register Map**

| Offset | Name         | Type | Reset                                    | Description                          | See page |

## 17.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

**Register 1: Watchdog Load (WDTLOAD), offset 0x000**

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

**Watchdog Load (WDTLOAD)**

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x000

Type RW, reset 0xFFFF.FFFF

|       |         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

|-----------|----------|------|-------------|-------------------------------------------------------------|
| 31:0      | WDTVALUE | RO   | 0xFFFF.FFFF | Watchdog Value<br>Current value of the 32-bit down counter. |

### Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled by setting the INTEN bit, all subsequent writes to the INTEN bit are ignored. The only mechanisms that can re-enable writes to this bit are a hardware reset or a software reset initiated by setting the appropriate bit in the **Watchdog Timer Software Reset (SRWD)** register.

**Important:** Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The WRC bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for WRC=1 prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock and therefore does not have a WRC bit.

Once this bit is set, it can only be cleared by a hardware reset or a software reset initiated by setting the appropriate bit in the <b>Watchdog Timer Software Reset (SRWD)</b> register.<br>1 Interrupt event enabled. Once enabled, all writes are ignored. Setting this bit enables the Watchdog Timer. |

**Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C**

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Write to this register when a watchdog time-out interrupt has occurred to properly service the Watchdog. Value for a read or reset is indeterminate.

**Note:** Locking the watchdog registers by using the **WDTLOCK** register does not affect the **WDTICR** register and allows interrupts to always be serviced. Thus, a write at any time of the **WDTICR** register clears the **WDTMIS** register and reloads the 32-bit counter from the **WDTLOAD** register. The **WDTICR** register should only be written when interrupts have triggered and need to be serviced.

**Watchdog Interrupt Clear (WDTICR)**

|           |          |      | 1         | If the microcontroller is stopped with a debugger, the watchdog timer stops counting. Once the microcontroller is restarted, the watchdog timer resumes counting.                             |
| 7:0       | reserved | RO   | 0x00      | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

**Register 8: Watchdog Lock (WDTLOCK), offset 0xC00**

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers, except for the **Watchdog Test (WDTTEST)** register. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

**Watchdog Lock (WDTLOCK)**

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0xC00

Type RW, reset 0x0000.0000

| Bit/Field | Name    | Type | Reset       | Description   |
|-----------|---------|------|-------------|---------------|
| 31:0      | WDTLOCK | RW   | 0x0000.0000 | Watchdog Lock |

A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value reapplies the lock, preventing any register updates, except for the **WDTTEST** register. Avoid writes to the **WDTTEST** register when the watchdog registers are locked.

A read of this register returns the following values:

| Value       | Description |
|-------------|-------------|
| 0x0000.0001 | Locked      |
| 0x0000.0000 | Unlocked    |

Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

## 18 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. Two identical converter modules are included, which share 24 input channels.

The TM4C129DNCZAD ADC module features 12-bit conversion resolution and supports 24 input channels, plus an internal temperature sensor. Each ADC module contains four programmable sequencers allowing the sampling of multiple analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. In addition, the conversion value can optionally be diverted to a digital comparator module. Each ADC module provides eight digital comparators. Each digital comparator evaluates the ADC conversion value against its two user-defined values to determine the operational range of the signal. The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. A phase shifter can delay the start of sampling by a specified phase angle. When using both ADC modules, it is possible to configure the converters to start the conversions coincidentally or within a relative phase from each other, see “Sample Phase Control” on page 1177.

The TM4C129DNCZAD microcontroller provides two ADC modules with each having the following features:

- 24 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of one million samples/second
- Optional, programmable phase delay
- Sample and hold window programmability
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - PWM
  - GPIO
- Hardware averaging of up to 64 samples
- Eight digital comparators

- Converter uses two external reference signals (VREFA+ and VREFA- ) or VDDA and GNDA as the voltage reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Dedicated channel for each sample sequencer
  - ADC module uses burst requests for DMA
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate ADC clock

## 18.1 Block Diagram

The TM4C129DNCZAD microcontroller contains two identical Analog-to-Digital Converter modules. These two modules, ADC0 and ADC1, share the same 24 analog input channels. Each ADC module operates independently and can therefore execute different sample sequences, sample any of the analog input channels at any time, and generate different interrupts and triggers. Figure 18-1 on page 1171 shows how the two modules are connected to analog inputs and the system bus.

**Figure 18-1. Implementation of Two ADC Blocks**

Figure 18-2 on page 1172 provides details on the internal configuration of the ADC controls and data registers.

Figure 18-2. ADC Module Block Diagram

## 18.2 Signal Description

The following table lists the external signals of the ADC module and describes the function of each. The AINx signals are analog functions for some GPIO signals. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the ADC signals. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 741. The VREF+ and VREF- signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function and are not 5-V tolerant.

Table 18-1. ADC Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                          |
|----------|------------|--------------------------|----------|-------------|--------------------------------------|
| AIN0     | G2         | PE3                      | I        | Analog      | Analog-to-digital converter input 0. |

| AIN23    | B8         | PP6                      | I        | Analog      | Analog-to-digital converter input 23.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| VREFA+   | F4         | fixed                    | -        | Analog      | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 30-44 on page 1935.                                                                                                                               |
| VREFA-   | G5         | fixed                    | -        | Analog      | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 30-44 on page 1935. |

## 18.3 Functional Description

The TM4C129DNCZAD ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approaches found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the processor. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence. In addition, the  $\mu$ DMA can be used to more efficiently move data from the sample sequencers without CPU intervention.

### 18.3.1 Sample Sequencers

The sampling control and data capture is handled by the sample sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 18-2 on page 1174 shows the maximum number of samples that each sequencer can capture and its corresponding FIFO depth. Each sample that is captured is stored in the FIFO. In this implementation, each FIFO entry is a 32-bit word, with the lower 12 bits containing the conversion result.

**Table 18-2. Samples and FIFO Depth of Sequencers**

| Sequencer | Number of Samples | Depth of FIFO |
|-----------|-------------------|---------------|
| SS3       | 1                 | 1             |
| SS2       | 4                 | 4             |
| SS1       | 4                 | 4             |
| SS0       | 8                 | 8             |

For a given sample sequence, each sample is defined by bit fields in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn)**, **ADC Sample Sequence Extended Input Multiplexer Select (ADCSEMUXn)** and **ADC Sample Sequence Control (ADCSSCTLn)** registers, where "n" corresponds to the sequence number. The **ADCSSMUXn** and **ADCSEMUXn** fields select the input pin, while the **ADCSSCTLn** fields contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample sequencers are enabled by setting the respective **ASENn** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register and should be configured before being enabled. Sampling is then initiated by setting the **SSn** bit in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. In addition, sample sequences may be initiated on multiple ADC modules simultaneously using the **GSYNC** and **SYNCWAIT** bits in the **ADCPSSI** register during the configuration of each ADC module. For more information on using these bits, refer to page 1221.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence are allowed. In the **ADCSSCTLn** register, the **IEn** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END** bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the **END** bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFO)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTATn)** registers along with **FULL** and **EMPTY** status flags. If a write is attempted when the FIFO is full, the write does not occur and an overflow condition is indicated. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

### 18.3.2 Module Control

Outside of the sample sequencers, the remainder of the control logic is responsible for tasks such as:

- Interrupt generation
- DMA operation

- Sequence prioritization
- Trigger configuration
- Comparator configuration
- External voltage reference
- Sample phase control
- Module clocking

### 18.3.2.1 Interrupts

The register configurations of the sample sequencers and digital comparators dictate which events generate raw interrupts, but do not have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signals are controlled by the state of the MASK bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADC RIS)** register, which shows the raw status of the various interrupt signals; and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows active interrupts that are enabled by the **ADCIM** register. Sequencer interrupts are cleared by writing a 1 to the corresponding IN bit in **ADCISC**. Digital comparator interrupts are cleared by writing a 1 to the **ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)** register.

### 18.3.2.2 DMA Operation

DMA may be used to increase efficiency by allowing each sample sequencer to operate independently and transfer data without processor intervention or reconfiguration.

The ADC asserts single and burst  $\mu$ DMA request signals (dma\_sreq and dma\_req) to the  $\mu$ DMA controller based on the FIFO level. The dma\_req signal is generated when the FIFO in question is half-full (that is, at 4 samples for SS0, 2 samples for SS1 and SS2, and at 1 sample for SS3). If, for example, the **ADCSSCTL0** register has six samples to transfer, a burst of four values occurs followed by two single transfers (dma\_sreq). The dma\_done signals (one per sample sequencer) are sent to the ADC to allow for a triggering of DMAINRn interrupt bits in the **ADCRIS** register. The  $\mu$ DMA is enabled for a specific sample sequencer by setting the appropriate ADENn bit in the **ADCACTSS** register at offset 0x000.

To use the  $\mu$ DMA with the ADC module, the application must enable the ADC channel through **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA.

Refer to the “Micro Direct Memory Access ( $\mu$ DMA)” on page 677 for more details about programming the  $\mu$ DMA controller.

### 18.3.2.3 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active sample sequencer units with the same priority do not provide consistent results, so software must ensure that all active sample sequencer units have a unique priority value.

### 18.3.2.4 Sampling Events

Sample triggering for each sample sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. Trigger sources include processor (default), analog comparators, an external signal on a GPIO specified by the **GPIO ADC Control (GPIOADCCTL)** register, a GP Timer, a

PWM generator, and continuous sampling. The processor triggers sampling by setting the SSx bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register.

Care must be taken when using the continuous sampling trigger. If a sequencer's priority is too high, it is possible to starve other lower priority sequencers. Generally, a sample sequencer using continuous sampling should be set to the lowest priority. Continuous sampling can be used with a digital comparator to cause an interrupt when a particular voltage is seen on an input.

### 18.3.2.5 Sample and Hold Window Control

The ADC module provides the capability of programming the sample and hold window of each step in a sequence through the **ADC Sample Sequence n Sample and Hold Time (ADCSSTSHn)** register. Each TSHn field can be written with a different sample and hold width, which is represented in ADC clocks. The table below gives the allowed encodings:

**Table 18-3. Sample and Hold Width in ADC Clocks**

| TSHn Encoding | N <sub>SH</sub> |
|---------------|-----------------|
| 0x0           | 4               |
| 0x1           | reserved        |
| 0x2           | 8               |
| 0x3           | reserved        |
| 0x4           | 16              |
| 0x5           | reserved        |
| 0x6           | 32              |
| 0x7           | reserved        |
| 0x8           | 64              |
| 0x9           | reserved        |
| 0xA           | 128             |
| 0xB           | reserved        |
| 0xC           | 256             |
| 0xD-0xF       | reserved        |

Since both source resistance and conversion frequency are functions of the sample and hold number (N<sub>SH</sub>), the system designer must evaluate how changing this value can effect system performance. Source resistance can be calculated by the following equation:

$$R_S = ((N_{SH} * T_{ADC}) / C_{ADC} * \ln(2^N)) - R_{ADC}$$

where:

- N<sub>SH</sub> is the number of ADC conversion clock periods in the sample time
- T<sub>ADC</sub> is the ADC conversion clock period, which is 1/16 MHz for 1 Msps
- C<sub>ADC</sub> is the ADC equivalent input capacitance, which equals 10 pF
- N is the resolution which is 12-bits
- R<sub>ADC</sub> is the ADC equivalent input resistance which is 2.5 kΩ

Conversion frequency can be calculated using the following equation:

$$F_{\text{CONV}} = 1/((N_{\text{SH}} + 12) \cdot T_{\text{ADC}})$$

where:

- $N_{\text{SH}}$  is the number of ADC conversion clock periods in the sample time
- $T_{\text{ADC}}$  is the ADC conversion clock period, which is 1/16 MHz for 1 Msps

These two equations show that when  $N_{\text{SH}}$  is increased,  $F_{\text{CONV}}$  is reduced and  $R_{\text{S}}$  is increased:

**Table 18-4.  $R_{\text{S}}$  and  $F_{\text{CONV}}$  Values with Varying  $N_{\text{SH}}$  Values and  $T_{\text{ADC}} = 1/16$  MHz**

| $N_{\text{SH}}$             | 4    | 8     | 16    | 32     | 64     | 128    | 256     |
|-----------------------------|------|-------|-------|--------|--------|--------|---------|
| $R_{\text{S}}$ ( $\Omega$ ) | 506  | 3,511 | 9,522 | 21,545 | 45,590 | 93,680 | 189,859 |
| $F_{\text{CONV}}$ (Ksps)    | 1000 | 800   | 571   | 364    | 211    | 114    | 60      |

The system designer must take into consideration both of these factors for optimal ADC operation.

### 18.3.2.6 Sample Phase Control

The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. If the converters are running at the same sample rate, they may be configured to start the conversions coincidentally or one ADC may be programmed to lag up to 15 clock cycles relative to the other ADC. The sample time can be delayed from the standard sampling time by programming the PHASE field in the **ADC Sample Phase Control (ADCSPC)** register. Figure 18-3 on page 1177 shows an example of various phase relationships at a 1 Msps rate.

**Figure 18-3. ADC Sample Phases**

This feature can be used to double the sampling rate of an input. Both ADC Module 0 and ADC Module 1 can be programmed to sample the same input. ADC module 0 can sample at the standard position (the PHASE field in the **ADCSPC** register is 0x0). ADC Module 1 can be configured to sample with a phase lag (PHASE is nonzero). For a sample rate of samples/second at , the TSHn field of all of the sequencer samples of both ADCs must be programmed to 0x0 and the PHASE field of one of the ADC modules must be set to 0x8. The two modules can be be synchronized using the GSYNC and SYNCWAIT bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. Software can then combine the results from the two modules to create a sample rate of one million samples/second at 16MHz as shown in Figure 18-4 on page 1178.

**Figure 18-4. Doubling the ADC Sample Rate**

Using the **ADCSPC** register, ADC0 and ADC1 may provide a number of interesting applications:

- Coincident continuous sampling of different signals. The sample sequence steps run coincidentally in both converters. In this situation, the TSHn of matching sample steps of both ADC module sequencers must be the same and the PHASE field must be 0x0 in both ADC module **ADCSPC** registers. The TSHn field is found in the **ADC Sample Sequence n Sample and Hold Time (ADCSSTSHn)** register.
  - ADC Module 0, **ADCSPC** = 0x0, sampling AIN0
  - ADC Module 1, **ADCSPC** = 0x0, sampling AIN1
- Skewed sampling of the same signal. The skew is determined by both the TSHn field in the **ADCSSTSHn** registers and the PHASE field in the **ADCSPC** register. For the fastest skewed sample rate, all TSHn fields must be programmed to 0x0. If TSHn=0x0 for all sequencers and the PHASE field of one ADC is 0x8, the configuration doubles the conversion bandwidth of a single input when software combines the results as shown in Figure 18-5 on page 1179.
  - ADC Module 0, **ADCSPC** = 0x0, sampling AIN0
  - ADC Module 1, **ADCSPC** = 0x8, sampling AIN0

Note that it is not required that the TSHn fields be the same in a skewed sample. If an application has varying analog input resistance, then TSHn and PHASE may vary according to operational requirements.

Figure 18-5. Skewed Sampling

### 18.3.2.7 Module Clocking

The ADC digital block is clocked by the system clock and the ADC analog block is clocked from a separate conversion clock (ADC Clock). The ADC clock frequency can be up to 32 MHz to generate a conversion rate of 2 Msps. A 16 MHz ADC clock provides a 1 Msps sampling rate. There are three sources of the ADC clock:

- Divided PLL VCO. The PLL VCO frequency can be configured to generate up to a 32-MHz clock for a conversion rate of 2 Msps. The CS field in the **ADCCC** register must be programmed to 0x0 to select the PLL VCO and the CLKDIV field is used to set the appropriate clock divisor for the desired frequency.
- 16 MHz PIOSC. Using the PIOSC provides a conversion rate near 1 Msps. To use the PIOSC to clock the ADC, first power up the PLL and then enable the PIOSC in the CS bit field in the **ADCCC** register, then disable the PLL.
- MOSC. The MOSC clock source must be 16 MHz for a 1 Msps conversion rate and 32 MHz for a 2 Msps conversion rate.

The system clock must be at the same frequency or higher than the ADC clock. All ADC modules share the same clock source to facilitate the synchronization of data samples between conversion units, the selection and programming of which is provided by ADC0's **ADCCC** register. The ADC modules do not run at different conversion rates.

### 18.3.2.8 Busy Status

The BUSY bit of the **ADCACTSS** register is used to indicate when the ADC is busy with a current conversion. When there are no triggers pending which may start a new conversion in the immediate cycle or next few cycles, the BUSY bit reads as 0. Software must read the status of the BUSY bit as clear before disabling the ADC clock by writing to the **Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC)** register.

### 18.3.2.9 Dither Enable

The **ADCCTL** register provides a dither enable bit to reduce random noise in ADC sampling. The **DITHER** bit is enabled by default at reset. Dither mode can be disabled by clearing the **DITHER** bit in the **ADCCTL** register.

### 18.3.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off, and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 1223). A single averaging circuit has been implemented, thus all input channels receive the same amount of averaging whether they are single-ended or differential.

Figure 18-6 shows an example in which the **ADCSAC** register is set to 0x2 for 4x hardware oversampling and the **IE1** bit is set for the sample sequence, resulting in an interrupt after the second averaged value is stored in the FIFO.

**Figure 18-6. Sample Averaging Example**

### 18.3.4 Analog-to-Digital Converter

The Analog-to-Digital Converter (ADC) module uses a Successive Approximation Register (SAR) architecture to deliver a 12-bit, low-power, high-precision conversion value. The successive approximation uses a switched capacitor array to perform the dual functions of sampling and holding the signal as well as providing the 12-bit DAC operation.

Figure 18-7 shows the ADC input equivalency diagram; for parameter values, see “Analog-to-Digital Converter (ADC)” on page 1935.

**Figure 18-7. ADC Input Equivalency Diagram**

The ADC operates from both the 3.3-V analog and 1.2-V digital power supplies. The ADC clock can be configured to reduce power consumption when ADC conversions are not required (see “System Control” on page 243). The analog inputs are connected to the ADC through specially balanced input paths to minimize the distortion and cross-talk on the inputs. Detailed information on the ADC power supplies and analog inputs can be found in “Analog-to-Digital Converter (ADC)” on page 1935.

#### 18.3.4.1 Voltage Reference

The ADC uses internal signals  $V_{\text{REFP}}$  and  $V_{\text{REFN}}$  as references to produce a conversion value from the selected analog input.  $V_{\text{REFP}}$  can be connected to either  $V_{\text{REFA+}}$  or  $V_{\text{DDA}}$  and  $V_{\text{REFN}}$  can be connected to either  $V_{\text{REFA-}}$  or  $V_{\text{GND}}$  as configured by the **VREF** bit in the **ADC Control (ADCCTL)** register, as shown in Figure 18-8.

**Figure 18-8. ADC Voltage Reference**

The range of this conversion value is from 0x000 to 0xFFF. In single-ended-input mode, the 0x000 value corresponds to the voltage level on VREFN; the 0xFFF value corresponds to the voltage level on VREFP. This configuration results in a resolution that can be calculated using the following equation:

$$\text{mV per ADC code} = (\text{VREFP} - \text{VREFN}) / 4096$$

While the analog input pads can handle voltages beyond this range, the analog input voltages must remain within the limits prescribed by Table 30-44 on page 1935 to produce accurate results. The  $V_{\text{REFA+}}$  and  $V_{\text{REFA-}}$  specifications define the useful range for the external voltage references on VREFA+ and VREFA-, see Table 30-44 on page 1935. Care must be taken to supply a reference voltage of acceptable quality. Figure 18-9 on page 1183 shows the ADC conversion function of the analog inputs.

Figure 18-9. ADC Conversion Result

### 18.3.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the Dn bit in the **ADCSSCTL0n** register in a step's configuration nibble.

When a sequence step is configured for differential sampling, the input pair to sample must be configured in the **ADCSSMUXn** register. Differential pair 0 samples analog inputs 0 and 1; differential pair 1 samples analog inputs 2 and 3; and so on (see Table 18-5 on page 1183). The ADC does not support other differential pairings such as analog input 0 with analog input 3.

Table 18-5. Differential Sampling Pairs

| Differential Pair | Analog Inputs |
|-------------------|---------------|
| 0                 | 0 and 1       |
| 1                 | 2 and 3       |
| 2                 | 4 and 5       |
| 3                 | 6 and 7       |
| 4                 | 8 and 9       |
| 5                 | 10 and 11     |
| 6                 | 12 and 13     |

**Table 18-5. Differential Sampling Pairs (continued)**

| Differential Pair | Analog Inputs |
|-------------------|---------------|
| 7                 | 14 and 15     |
| 8                 | 16 and 17     |
| 9                 | 18 and 19     |
| 10                | 20 and 21     |
| 11                | 22 and 23     |

The voltage sampled in differential mode is the difference between the odd and even channels:

- Input Positive Voltage:  $V_{IN+} = V_{IN\_EVEN}$  (even channel)
- Input Negative Voltage:  $V_{IN-} = V_{IN\_ODD}$  (odd channel)

The input differential voltage is defined as:  $V_{IN_D} = V_{IN+} - V_{IN-}$ , therefore:

- If  $V_{IN_D} = 0$ , then the conversion result = 0x800
- If  $V_{IN_D} > 0$ , then the conversion result > 0x800 (range is 0x800–0xFFFF)
- If  $V_{IN_D} < 0$ , then the conversion result < 0x800 (range is 0–0x800)

When using differential sampling, the following definitions are relevant:

- Input Common Mode Voltage:  $V_{IN\_CM} = (V_{IN+} + V_{IN-}) / 2$
- Reference Positive Voltage:  $V_{REFP}$
- Reference Negative Voltage:  $V_{REFN}$
- Reference Differential Voltage:  $V_{REF_D} = V_{REFP} - V_{REFN}$
- Reference Common Mode Voltage:  $V_{REF\_CM} = (V_{REFP} + V_{REFN}) / 2$

The following conditions provide optimal results in differential mode:

- Both  $V_{IN\_EVEN}$  and  $V_{IN\_ODD}$  must be in the range of ( $V_{REFP}$  to  $V_{REFN}$ ) for a valid conversion result
- The maximum possible differential input swing, or the maximum differential range, is:  $-V_{REF_D}$  to  $+V_{REF_D}$ , so the maximum peak-to-peak input differential signal is  $(+V_{REF_D} - -V_{REF_D}) = 2 * V_{REF_D} = 2 * (V_{REFP} - V_{REFN})$
- In order to take advantage of the maximum possible differential input swing,  $V_{IN\_CM}$  should be very close to  $V_{REF\_CM}$ , see Table 30-44 on page 1935.

If  $V_{IN\_CM}$  is not equal to  $V_{REF\_CM}$ , the differential input signal may clip at either maximum or minimum voltage, because either single ended input can never be larger than  $V_{REFP}$  or smaller than  $V_{REFN}$ , and it is not possible to achieve full swing. Thus any difference in common mode between the input voltage and the reference voltage limits the differential dynamic range of the ADC.

Because the maximum peak-to-peak differential signal voltage is  $2 * (V_{REFP} - V_{REFN})$ , the ADC codes are interpreted as:

$$\text{mV per ADC code} = (2 * (\text{VREFP} - \text{VREFN})) / 4096$$

Figure 18-10 shows how the differential voltage,  $\Delta V$ , is represented in ADC codes.

**Figure 18-10. Differential Voltage Representation**

### 18.3.6 Internal Temperature Sensor

The temperature sensor serves two primary purposes: 1) to notify the system that internal temperature is too high or low for reliable operation and 2) to provide temperature measurements for calibration of the Hibernate module RTC trim value.

The temperature sensor does not have a separate enable, because it also contains the bandgap reference and must always be enabled. The reference is supplied to other analog modules; not just the ADC. In addition, the temperature sensor has a second power-down input in the 3.3 V domain which provides control by the Hibernation module.

The internal temperature sensor converts a temperature measurement into a voltage. This voltage value,  $V_{\text{TSENS}}$ , is given by the following equation (where TEMP is the temperature in °C):

$$V_{\text{TSENS}} = 2.7 - ((\text{TEMP} + 55) / 75)$$

This relation is shown in Figure 18-11 on page 1186.

Figure 18-11. Internal Temperature Sensor Characteristic

The temperature sensor reading can be sampled in a sample sequence by setting the TS<sub>n</sub> bit in the **ADCSCTL<sub>n</sub>** register. The sample and hold width should be configured for at least 16 ADC clocks using the **ADCSSTSH<sub>n</sub>** register. The temperature reading from the temperature sensor can also be given as a function of the ADC value. The following formula calculates temperature (TEMP in °C) based on the ADC reading (ADC<sub>CODE</sub>, given as an unsigned decimal number from 0 to 4095) and the maximum ADC voltage range (VREFP - VREFN):

$$TEMP = 147.5 - ((75 * (VREFP - VREFN) \times ADC_{CODE}) / 4096)$$

### 18.3.7 Digital Comparator Unit

An ADC is commonly used to sample an external signal and to monitor its value to ensure that it remains in a given range. To automate this monitoring procedure and reduce the amount of processor overhead that is required, each module provides eight digital comparators.

Conversions from the ADC that are sent to the digital comparators are compared against the user programmable limits in the **ADC Digital Comparator Range (ADCDCMP<sub>n</sub>)** registers. The ADC can be configured to generate an interrupt depending on whether the ADC is operating within the low, mid or high-band region configured in the ADCDCMP<sub>n</sub> bit fields. The digital comparators four operational modes (Once, Always, Hysteresis Once, Hysteresis Always) can be additionally applied to the interrupt configuration.

#### 18.3.7.1 Output Functions

ADC conversions can either be stored in the ADC Sample Sequence FIFOs or compared using the digital comparator resources as defined by the SnDCOP bits in the **ADC Sample Sequence n Operation (ADCSOP<sub>n</sub>)** register. These selected ADC conversions are used by their respective digital comparator to monitor the external signal. Each comparator has two possible output functions: processor interrupts and triggers.

Each function has its own state machine to track the monitored signal. Even though the interrupt and trigger functions can be enabled individually or both at the same time, the same conversion

data is used by each function to determine if the right conditions have been met to assert the associated output.

### **Interrupts**

The digital comparator interrupt function is enabled by setting the CIE bit in the **ADC Digital Comparator Control (ADCDCCTLn)** register. This bit enables the interrupt function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, and the DCONSSx bit is set in the **ADCIM** register, an interrupt is sent to the interrupt controller.

**Note:** For a 1 Msp/s rate, as the system clock frequency approaches the ADC clock frequency, it is recommended that the application use the  $\mu$ DMA to store conversion data from the FIFO to memory before processing rather than an interrupt-driven single data read. Using the  $\mu$ DMA to store multiple samples before interrupting the processor amortizes interrupt overhead across multiple transfers and prevents loss of sample data.

**Note:** Only a single DCONSSn bit should be set at any given time. Setting more than one of these bits results in the INRDC bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

### **Triggers**

The digital comparator trigger function is enabled by setting the CTE bit in the **ADCDCCTLn** register. This bit enables the trigger function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, the corresponding digital comparator trigger to the PWM module is asserted.

## **18.3.7.2 Operational Modes**

Four operational modes are provided to support a broad range of applications and multiple possible signaling requirements: Always, Once, Hysteresis Always, and Hysteresis Once. The operational mode is selected using the CIM or CTM field in the **ADCDCCTLn** register.

### **Always Mode**

In the Always operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria. The result is a string of assertions on the interrupt or trigger while the conversions are within the appropriate range.

### **Once Mode**

In the Once operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria, and the previous ADC conversion value did not. The result is a single assertion of the interrupt or trigger when the conversions are within the appropriate range.

### **Hysteresis-Always Mode**

The Hysteresis-Always operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Always mode, the associated interrupt or trigger is asserted in the following cases: 1) the ADC conversion value meets its comparison criteria or 2) a previous ADC conversion value has met the comparison criteria, and the hysteresis condition has not been cleared by entering the opposite region. The result is a string of assertions on the interrupt or trigger that continue until the opposite region is entered.

### Hysteresis-Once Mode

The Hysteresis-Once operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Once mode, the associated interrupt or trigger is asserted only when the ADC conversion value meets its comparison criteria, the hysteresis condition is clear, and the previous ADC conversion did not meet the comparison criteria. The result is a single assertion on the interrupt or trigger.

### 18.3.7.3 Function Ranges

The two comparison values, COMP0 and COMP1, in the **ADC Digital Comparator Range (ADCDCMPn)** register effectively break the conversion area into three distinct regions. These regions are referred to as the low-band (less than COMP0), mid-band (greater than COMP0 but less than or equal to COMP1), and high-band (greater than or equal to COMP1) regions. COMP0 and COMP1 may be programmed to the same value, effectively creating two regions, but COMP1 must always be greater than or equal to the value of COMP0. A COMP1 value that is less than COMP0 generates unpredictable results.

#### Low-Band Operation

To operate in the low-band region, the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x0. This setting causes interrupts or triggers to be generated in the low-band region as defined by the programmed operational mode. An example of the state of the interrupt/trigger signal in the low-band region for each of the operational modes is shown in Figure 18-12 on page 1188. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

**Figure 18-12. Low-Band Operation (CIC=0x0 and/or CTC=0x0)**

### Mid-Band Operation

To operate in the mid-band region, the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x1. This setting causes interrupts or triggers to be generated in the mid-band region according to the operation mode. Only the Always and Once operational modes are available in the mid-band region. An example of the state of the interrupt/trigger signal in the mid-band region for each of the allowed operational modes is shown in Figure 18-13 on page 1189. Note that a "0" in a column following the operational mode name (Always or Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

**Figure 18-13. Mid-Band Operation (CIC=0x1 and/or CTC=0x1)**

### High-Band Operation

To operate in the high-band region, the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x3. This setting causes interrupts or triggers to be generated in the high-band region according to the operation mode. An example of the state of the interrupt/trigger signal in the high-band region for each of the allowed operational modes is shown in Figure 18-14 on page 1190. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 18-14. High-Band Operation (CIC=0x3 and/or CTC=0x3)

## 18.4 Initialization and Configuration

### 18.4.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps: enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the sample sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock using the **RCGCADC** register (see page 399).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 386). To find out which GPIO ports to enable, refer to “Signal Description” on page 1172.
3. Set the GPIO AFSEL bits for the ADC input pins (see page 771). To determine which GPIOs to configure, see Table 29-4 on page 1873.
4. Configure the AINx signals to be analog inputs by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register (see page 782).
5. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 787) in the associated GPIO block.
6. If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority and Sample Sequencer 3 as the lowest priority.

## 18.4.2 Sample Sequencer Configuration

Configuration of the sample sequencers is slightly more complex than the module initialization because each sample sequencer is completely programmable.

The configuration for each sample sequencer should be as follows:

1. Ensure that the sample sequencer is disabled by clearing the corresponding ASENn bit in the **ADCACTSS** register. Programming of the sample sequencers is allowed without having them enabled. Disabling the sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
2. Configure the trigger event for the sample sequencer in the **ADCEMUX** register.
3. When using a PWM generator as the trigger source, use the **ADC Trigger Source Select (ADCTSSEL)** register to specify in which PWM module the generator is located. The default register reset selects PWM module 0 for all generators.
4. For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUXn** and **ADCSEMUXn** registers.
5. For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTLn** register. When programming the last nibble, ensure that the END bit is set. Failure to set the END bit causes unpredictable behavior.
6. If interrupts are to be used, set the corresponding MASK bit in the **ADCIM** register.
7. Enable the sample sequencer logic by setting the corresponding ASENn bit in the **ADCACTSS** register.

## 18.5 Register Map

Table 18-6 on page 1191 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to that ADC module's base address of:

- ADC0: 0x4003.8000
- ADC1: 0x4003.9000

Note that the ADC module clock must be enabled before the registers can be programmed (see page 399). There must be a delay of 3 system clocks after the ADC module clock is enabled before any ADC module registers are accessed.

**Table 18-6. ADC Register Map**

| Offset | Name     | Type | Reset       | Description                    | See page |
|--------|----------|------|-------------|--------------------------------|----------|
| 0x000  | ADCACTSS | RW   | 0x0000.0000 | ADC Active Sample Sequencer    | 1195     |
| 0x004  | ADCRIS   | RO   | 0x0000.0000 | ADC Raw Interrupt Status       | 1197     |
| 0x008  | ADCIM    | RW   | 0x0000.0000 | ADC Interrupt Mask             | 1200     |

## **18.6 Register Descriptions**

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

**Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000**

This register controls the activation of the sample sequencers. Each sample sequencer can be enabled or disabled independently.

**ADC Active Sample Sequencer (ADCACTSS)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x000

Type RW, reset 0x0000.0000

**Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004**

This register shows the status of the raw interrupt signal of each sample sequencer. These bits may be polled by software to look for interrupt conditions without sending the interrupts to the interrupt controller.

**ADC Raw Interrupt Status (ADCRIS)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x004

Type RO, reset 0x0000.0000

**Register 3: ADC Interrupt Mask (ADCIM), offset 0x008**

This register controls whether the sample sequencer and digital comparator raw interrupt signals are sent to the interrupt controller. Each raw interrupt signal can be masked independently.

**Note:** For a 1 Msps rate, as the system clock frequency approaches the ADC clock frequency, it is recommended that the application use the  $\mu$ DMA to store conversion data from the FIFO to memory before processing rather than an interrupt-driven single data read. Using the  $\mu$ DMA to store multiple samples before interrupting the processor amortizes interrupt overhead across multiple transfers and prevents loss of sample data.

**Note:** Only a single DCONSSn bit should be set at any given time. Setting more than one of these bits results in the INRDC bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

**ADC Interrupt Mask (ADCIM)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x008

Type RW, reset 0x0000.0000

## Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing sample sequencer interrupt conditions and shows the status of interrupts generated by the sample sequencers and the digital comparators which have been sent to the interrupt controller. When read, each bit field is the logical AND of the respective INR and MASK bits. Sample sequencer interrupts are cleared by writing a 1 to the corresponding bit position. Digital comparator interrupts are cleared by writing a 1 to the appropriate bits in the **ADCDCISC** register. If software is polling the **ADCRIS** instead of generating interrupts, the sample sequence INRn bits are still cleared via the **ADCISC** register, even if the INn bit is not set.

### ADC Interrupt Status and Clear (ADCISC)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x00C

Type RW1C, reset 0x0000.0000

**Register 5: ADC Overflow Status (ADCOSTAT), offset 0x010**

This register indicates overflow conditions in the sample sequencer FIFOs. Once the overflow condition has been handled by software, the condition can be cleared by writing a 1 to the corresponding bit position.

**ADC Overflow Status (ADCOSTAT)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x010

Type RW1C, reset 0x0000.0000

|           |      |      |       | 0 The FIFO has not overflowed.                                                                                                                                                            |
|           |      |      |       | 1 The FIFO for Sample Sequencer 0 has hit an overflow condition, meaning that the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped. |
|           |      |      |       | This bit is cleared by writing a 1.                                                                                                                                                       |

**Register 6: ADC Event Multiplexer Select (ADCEMUX), offset 0x014**

The **ADCEMUX** selects the event (trigger) that initiates sampling for each sample sequencer. Each sample sequencer can be configured with a unique trigger source.

**ADC Event Multiplexer Select (ADCEMUX)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x014

Type RW, reset 0x0000.0000

**Register 7: ADC Underflow Status (ADCUSTAT), offset 0x018**

This register indicates underflow conditions in the sample sequencer FIFOs. The corresponding underflow condition is cleared by writing a 1 to the relevant bit position.

**ADC Underflow Status (ADCUSTAT)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x018

Type RW1C, reset 0x0000.0000

**Register 8: ADC Trigger Source Select (ADCTSSEL), offset 0x01C**

If a PWM Generator *n* is selected as a trigger source through the EM*n* bit field in the **ADC Event Multiplexer Select (ADCEMUX)** register, the **ADCTSSEL** register is programmed to identify in which PWM module instance the generator creating the trigger is located. The register resets to 0x0000.0000, which selects PWM module 0 for all generators. Note that field PS3 selects the PWM module that maps to Generator 3; PS2 selects the PWM module that maps to Generator 2, and so on.

**ADC Trigger Source Select (ADCTSSEL)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x01C

Type RW, reset 0x0000.0000

**Register 9: ADC Sample Sequencer Priority (ADCSSPRI), offset 0x020**

This register sets the priority for each of the sample sequencers. Out of reset, Sequencer 0 has the highest priority, and Sequencer 3 has the lowest priority. When reconfiguring sequence priorities, each sequence must have a unique priority for the ADC to operate properly.

**ADC Sample Sequencer Priority (ADCSSPRI)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x020

Type RW, reset 0x0000.3210

## Register 10: ADC Sample Phase Control (ADCSPC), offset 0x024

The **ADC Sample Phase Control (ADCSPC)** register is used to insert a delay in ADC module sampling. This feature can be used with the SYNCWAIT and GSYNC bit in the **ADCPSSI** register to provide concurrent sampling of two different signals by two different ADC modules or skewed sampling of two ADC modules to increase the effective sampling rate. For concurrent sampling, the PHASE field of each ADC module must be the same and the sample and hold times (TSHn) for the matching sample steps of each ADC must be the same. For example, both ADC0 and ADC1 would program PHASE = 0x0 in the **ADCSPC** register and might both have the following configuration for their **ADCSSTSH0** register:

- TSH7=0x4
- TSH6=0x2
- TSH5=0x2
- TSH4=0x8
- TSH3=0x6
- TSH2=0x2
- TSH1=0x4
- TSH0=0x2

For skewed sampling with a consistent phase lag, the TSHn field in the **ADCSSTSHn** register must be the same for all sample steps of an ADC and for both ADC Modules. The desired lag can be calculated by adding the sample and hold time (TSHn) to the twelve clock conversion time to determine the total number of clocks in a sample period. For example to create a 180.0° phase lag, the PHASE of the lagging ADC is calculated as:

$\text{PHASE} = (\text{TSHn} + 12)/2$ , where TSHn is in ADC\_Clocks

For situations where a predictable phase lag is not required, sample and hold times (TSHn) of ADC modules can vary.

**Note:** Care should be taken when the PHASE field is non-zero, as the resulting delay in sampling the AINx input may result in undesirable system consequences. The time from ADC trigger to sample is increased and could make the response time longer than anticipated. The added latency could have ramifications in the system design. Designers should carefully consider the impact of this delay.

**Register 11: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028**

This register provides a mechanism for application software to initiate sampling in the sample sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

This register also provides a means to configure and then initiate concurrent sampling on all ADC modules. To do this, the first ADC module should be configured. The **ADCPSSI** register for that module should then be written. The appropriate SS bits should be set along with the SYNCWAIT bit. Additional ADC modules should then be configured following the same procedure. Once the final ADC module is configured, its **ADCPSSI** register should be written with the appropriate SS bits set along with the GSYNC bit. All of the ADC modules then begin concurrent sampling according to their configuration.

**ADC Processor Sample Sequence Initiate (ADCPSSI)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x028

Type RW, reset -

**Register 12: ADC Sample Averaging Control (ADCSAC), offset 0x030**

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from  $2^{\text{AVG}}$  consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG=7 provides unpredictable results.

**ADC Sample Averaging Control (ADCSAC)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x030

Type RW, reset 0x0000.0000

## Register 13: ADC Digital Comparator Interrupt Status and Clear (ADCDISC), offset 0x034

This register provides status and acknowledgement of digital comparator interrupts. One bit is provided for each comparator.

### ADC Digital Comparator Interrupt Status and Clear (ADCDISC)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x034

Type RW1C, reset 0x0000.0000

**Register 14: ADC Control (ADCCTL), offset 0x038**

This register configures the voltage reference. The voltage references for the conversion can be VREFA+ and VREFA- or VDDA and GNDA. Note that values set in this register apply to all ADC modules, it is not possible to set one module to use internal references and another to use external references.

**ADC Control (ADCCTL)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x038

Type RW, reset 0x0000.0040

## Register 15: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register, along with the **ADCSSMUX0** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. If the corresponding EMUXn bit in the **ADCSSMUX0** register is set, the MUXn field in this register selects from AIN[23:16]. When the corresponding EMUXn bit is clear, the MUXn field selects from AIN[15:0]. This register is 32 bits wide and contains information for eight possible samples.

**Note:** Channels AIN[31:24] do not exist on this microcontroller. Configuring MUXn to be 0x8-0xF when the corresponding EMUXn bit is set results in undefined behavior.

**Register 16: ADC Sample Sequence Control 0 (ADCSSCTL0), offset 0x044**

This register contains the configuration information for each sample for a sequence executed with a sample sequencer. When configuring a sample sequence, the END bit must be set for the final sample, whether it be after the first sample, eighth sample, or any sample in between. This register is 32 bits wide and contains information for eight possible samples.

Software must set an ENDn bit somewhere within the sequence. Samples defined after the sample containing a set ENDn bit are not requested for conversion even though the fields may be non-zero.</p>  |

**Register 17: ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0), offset 0x048**

**Register 18: ADC Sample Sequence Result FIFO 1 (ADCSSFIFO1), offset 0x068**

**Register 19: ADC Sample Sequence Result FIFO 2 (ADCSSFIFO2), offset 0x088**

**Register 20: ADC Sample Sequence Result FIFO 3 (ADCSSFIFO3), offset 0x0A8**

**Important:** This register is read-sensitive. See the register description for details.

This register contains the conversion results for samples collected with the sample sequencer (the **ADCSSFIFO0** register is used for Sample Sequencer 0, **ADCSSFIFO1** for Sequencer 1, **ADCSSFIFO2** for Sequencer 2, and **ADCSSFIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCOSTAT** and **ADCUSTAT** registers.

**Register 21: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C**

**Register 22: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C**

**Register 23: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C**

**Register 24: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC**

This register provides a window into the sample sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO with the head and tail pointers both pointing to index 0. The **ADCSSFSTAT0** register provides status on FIFO0, which has 8 entries; **ADCSSFSTAT1** on FIFO1, which has 4 entries; **ADCSSFSTAT2** on FIFO2, which has 4 entries; and **ADCSSFSTAT3** on FIFO3 which has a single entry.

## Register 26: ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0), offset 0x054

This register determines which digital comparator receives the sample from the given conversion on Sample Sequence 0, if the corresponding SnDCOP bit in the **ADCSSOP0** register is set.

### ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x054  
 Type RW, reset 0x0000.0000

## Register 27: ADC Sample Sequence Extended Input Multiplexer Select 0 (ADCSEMUX0), offset 0x058

This register, along with the **ADCSSMUX0** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. If a bit in this register is set, the corresponding MUXn field in the **ADCSSMUX0** register selects from AIN[23:16]. When a bit in this register is clear, the corresponding MUXn field selects from AIN[15:0]. This register is 32 bits wide and contains information for eight possible samples.

Note that this register is not used when the differential channel designation is used (the Dn bit is set in the **ADCSSCTL0** register) because the **ADCSSMUX0** register can select all the available pairs.

### ADC Sample Sequence Extended Input Multiplexer Select 0 (ADCSEMUX0)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x058

Type RW, reset 0x0000.0000

## Register 28: ADC Sample Sequence 0 Sample and Hold Time (ADCSSTSH0), offset 0x05C

This register controls the sample period size for each sample of sequencer 0. Each sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1176.

**Note:** If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks (TSHn = 0x4).

**Table 18-7. Sample and Hold Width in ADC Clocks**

| TSHn Encoding | N <sub>SH</sub> |

**Register 29: ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1), offset 0x060****Register 30: ADC Sample Sequence Input Multiplexer Select 2 (ADCSSMUX2), offset 0x080**

This register, along with the **ADCSSMUX1** or **ADCSSMUX2** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 1 or 2. If the corresponding EMUXn bit in the **ADCSSMUX1** or **ADCSSMUX2** register is set, the MUXn field in this register selects from AIN[23:16]. When the corresponding EMUXn bit is clear, the MUXn field selects from AIN[15:0]. These registers are 16 bits wide and contain information for four possible samples. See the **ADCSSMUX0** register on page 1227 for detailed bit descriptions. The **ADCSSMUX1** register affects Sample Sequencer 1 and the **ADCSSMUX2** register affects Sample Sequencer 2.

**Note:** Channels AIN[31:24] do not exist on this microcontroller. Configuring MUXn to be 0x8-0xF when the corresponding EMUXn bit is set results in undefined behavior.

**Register 31: ADC Sample Sequence Control 1 (ADCSSCTL1), offset 0x064****Register 32: ADC Sample Sequence Control 2 (ADCSSCTL2), offset 0x084**

These registers contain the configuration information for each sample for a sequence executed with Sample Sequencer 1 or 2. When configuring a sample sequence, the END bit must be set for the final sample, whether it be after the first sample, fourth sample, or any sample in between. These registers are 16-bits wide and contain information for four possible samples. See the **ADCSSCTL0** register on page 1229 for detailed bit descriptions. The **ADCSSCTL1** register configures Sample Sequencer 1 and the **ADCSSCTL2** register configures Sample Sequencer 2.

**Register 33: ADC Sample Sequence 1 Operation (ADCSSOP1), offset 0x070****Register 34: ADC Sample Sequence 2 Operation (ADCSSOP2), offset 0x090**

This register determines whether the sample from the given conversion on Sample Sequence n is saved in the Sample Sequence n FIFO or sent to the digital comparator unit. The **ADCSSOP1** register controls Sample Sequencer 1 and the **ADCSSOP2** register controls Sample Sequencer 2.

## ADC Sample Sequence n Operation (ADCSSOPn)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x070

Type RW, reset 0x0000.0000

**Register 35: ADC Sample Sequence 1 Digital Comparator Select (ADCSSDC1), offset 0x074****Register 36: ADC Sample Sequence 2 Digital Comparator Select (ADCSSDC2), offset 0x094**

These registers determine which digital comparator receives the sample from the given conversion on Sample Sequence n if the corresponding SnDCOP bit in the **ADCSSOPn** register is set. The **ADCSSDC1** register controls the selection for Sample Sequencer 1 and the **ADCSSDC2** register controls the selection for Sample Sequencer 2.

**ADC Sample Sequence n Digital Comparator Select (ADCSSDCn)**

## Register 37: ADC Sample Sequence Extended Input Multiplexer Select 1 (ADCSEMUX1), offset 0x078

## Register 38: ADC Sample Sequence Extended Input Multiplexer Select 2 (ADCSEMUX2), offset 0x098

This register, along with the **ADCSSMUX1** or **ADCSSMUX2** register, defines the analog input configuration for each sample in a sequence executed with either Sample Sequencer 1 or 2. If a bit in this register is set, the corresponding MUXn field in the **ADCSSMUX1** or **ADCSSMUX2** register selects from AIN[23:16]. When a bit in this register is clear, the corresponding MUXn field selects from AIN[15:0]. This register is 16 bits wide and contains information for four possible samples. The **ADCSEMUX1** register controls Sample Sequencer 1 and the **ADCSEMUX2** register controls Sample Sequencer 2.

Note that this register is not used when the differential channel designation is used (the Dn bit is set in the **ADCSSCTL1** or **ADCSSCTL2** register) because the **ADCSSMUX1** or **ADCSSMUX2** register can select all the available pairs.

### ADC Sample Sequence Extended Input Multiplexer Select n (ADCSEMUXn)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x078  
 Type RW, reset 0x0000.0000

**Register 39: ADC Sample Sequence 1 Sample and Hold Time (ADCSSTSH1), offset 0x07C****Register 40: ADC Sample Sequence 2 Sample and Hold Time (ADCSSTSH2), offset 0x09C**

These registers control the sample period size for each sample step of sequencer 1 and sequencer 2. Each sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1176.

**Note:** If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks (TSHn = 0x4).

**Table 18-8. Sample and Hold Width in ADC Clocks**

## Register 41: ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3), offset 0x0A0

This register, along with the **ADCSEMUX3** register, defines the analog input configuration for the sample in a sequence executed with Sample Sequencer 3. If the EMUX0 bit in the **ADCSEMUX3** register is set, the MUX0 field in this register selects from AIN[23:16]. When the EMUX0 bit is clear, the MUX0 field selects from AIN[15:0]. This register is four bits wide and contains information for one possible sample. See the **ADCSSMUX0** register on page 1227 for detailed bit descriptions.

**Register 42: ADC Sample Sequence Control 3 (ADCSSCTL3), offset 0x0A4**

This register contains the configuration information for a sample executed with Sample Sequencer 3. This register is 4 bits wide and contains information for one possible sample. See the **ADCSSCTL0** register on page 1229 for detailed bit descriptions.

**Note:** When configuring a sample sequence in this register, the **END0** bit must be set.

|           |      |      |       | Value Description                                                                                                                                                      |
|           |      |      |       | 0 The analog inputs are not differentially sampled.                                                                                                                    |
|           |      |      |       | 1 The analog input is differentially sampled. The corresponding <b>ADCSSMUXn</b> nibble must be set to the pair number "i", where the paired inputs are "2i and 2i+1". |
|           |      |      |       | Because the temperature sensor does not have a differential option, this bit must not be set when the TS0 bit is set.                                                  |

**Register 43: ADC Sample Sequence 3 Operation (ADCSSOP3), offset 0x0B0**

This register determines whether the sample from the given conversion on Sample Sequence 3 is saved in the Sample Sequence 3 FIFO or sent to the digital comparator unit.

**ADC Sample Sequence 3 Operation (ADCSSOP3)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x0B0

Type RW, reset 0x0000.0000

**Value Description**

- |   |                                                                                                                                                            |
|---|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | The sample is saved in Sample Sequence FIFO3.                                                                                                              |
| 1 | The sample is sent to the digital comparator unit specified by the S0DCSEL bit in the <b>ADCSSDC03</b> register, and the value is not written to the FIFO. |

## Register 44: ADC Sample Sequence 3 Digital Comparator Select (ADCSSDC3), offset 0x0B4

This register determines which digital comparator receives the sample from the given conversion on Sample Sequence 3 if the corresponding SnDCOP bit in the **ADCSSOP3** register is set.

### ADC Sample Sequence 3 Digital Comparator Select (ADCSSDC3)

## Register 45: ADC Sample Sequence Extended Input Multiplexer Select 3 (ADCSEMUX3), offset 0x0B8

This register, along with the **ADCSSMUX3** register, defines the analog input configuration for the sample in a sequence executed with Sample Sequencer 3. If EMUX0 is set, the MUX0 field in the **ADCSSMUX3** register selects from AIN[23:16]. When EMUX0 is clear, the MUX0 field selects from AIN[15:0]. This register is 1 bit wide and contains information for one possible sample.

Note that this register is not used when the differential channel designation is used (the Dn bit is set in the **ADCSSCTL3** register) because the **ADCSSMUX3** register can select all the available pairs.

### ADC Sample Sequence Extended Input Multiplexer Select 3 (ADCSEMUX3)

## Register 46: ADC Sample Sequence 3 Sample and Hold Time (ADCSSTSH3), offset 0x0BC

This register controls the sample period size for the sample in sequencer 3. The sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1176

**Note:** If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks (TSHn = 0x4).

**Table 18-9. Sample and Hold Width in ADC Clocks**

## Register 47: ADC Digital Comparator Reset Initial Conditions (ADCDCRIC), offset 0xD00

This register provides the ability to reset any of the digital comparator interrupt or trigger functions back to their initial conditions. Resetting these functions ensures that the data that is being used by the interrupt and trigger functions in the digital comparator unit is not stale.

### ADC Digital Comparator Reset Initial Conditions (ADCDCRIC)

| 0                 | Disables the trigger function state machine. ADC conversion data is ignored by the trigger function.                                                                              |      |          |                                                                                                                                                                                               |
| 1                 | Enables the trigger function state machine. The ADC conversion data is used to determine if a trigger should be generated according to the programming of the CTC and CTM fields. |      |          |                                                                                                                                                                                               |

No additional interrupts are generated until the hysteresis condition is cleared by entering the opposite operational region.<br/>Note that the hysteresis modes are only defined for CTC encodings of 0x0 and 0x3.</p> |

**Register 56: ADC Digital Comparator Range 0 (ADCDCCMP0), offset 0xE40**

**Register 57: ADC Digital Comparator Range 1 (ADCDCCMP1), offset 0xE44**

**Register 58: ADC Digital Comparator Range 2 (ADCDCCMP2), offset 0xE48**

**Register 59: ADC Digital Comparator Range 3 (ADCDCCMP3), offset 0xE4C**

**Register 60: ADC Digital Comparator Range 4 (ADCDCCMP4), offset 0xE50**

**Register 61: ADC Digital Comparator Range 5 (ADCDCCMP5), offset 0xE54**

**Register 62: ADC Digital Comparator Range 6 (ADCDCCMP6), offset 0xE58**

**Register 63: ADC Digital Comparator Range 7 (ADCDCCMP7), offset 0xE5C**

This register defines the comparison values that are used to determine if the ADC conversion data falls in the appropriate operating region.

**Note:** The value in the COMP1 field must be greater than or equal to the value in the COMP0 field or unexpected results can occur.

#### ADC Digital Comparator Range n (ADCDCCMPn)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xE40

Type RW, reset 0x0000.0000

## Register 65: ADC Peripheral Configuration (ADCPC), offset 0xFC4

The **ADCPC** register provides information regarding the configuration of the peripheral.

### ADC Peripheral Configuration (ADCPC)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xFC4

Type RW, reset 0x0000.0007

**Register 66: ADC Clock Configuration (ADCCC), offset 0xFC8**

The **ADCCC** register controls the clock source for the ADC module.

**ADC Clock Configuration (ADCCC)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xFC8

Type RW, reset 0x0000.0001

## 19 Universal Asynchronous Receivers/Transmitters (UARTs)

The TM4C129DNCZAD controller includes eight Universal Asynchronous Receiver/Transmitter (UART) with the following features:

- Programmable baud-rate generator allowing speeds up to 7.5 Mbps for regular speed (divide by 16) and 15 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem functionality available on the following UARTs:
  - UART0 (modem flow control and modem status)
  - UART1 (modem flow control and modem status)
  - UART2 (modem flow control)
  - UART3 (modem flow control)
  - UART4 (modem flow control)
- EIA-485 9-bit support

- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
  - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock

## 19.1 Block Diagram

Figure 19-1. UART Module Block Diagram

## 19.2 Signal Description

The following table lists the external signals of the UART module and describes the function of each. The UART signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin

placements for these UART signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to choose the UART function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 788) to assign the UART signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 741.

## 19.3 Functional Description

Each TM4C129DNCZAD UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control (UARTCTL)** register (see page 1307). Transmit and receive are both enabled out of reset. Before any

control registers are programmed, the UART must be disabled by clearing the UARTEN bit in **UARTCTL**. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART module also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the **UARTCTL** register.

### 19.3.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 19-2 on page 1283 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

**Figure 19-2. UART Character Frame**

### 19.3.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divisor allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 1303) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 1304). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = \text{UARTSysClk} / (\text{ClkDiv} * \text{Baud Rate})$$

where *UARTSysClk* is the system clock connected to the UART, and *ClkDiv* is either 16 (if HSE in **UARTCTL** is clear) or 8 (if HSE is set). By default, this will be the main system clock described in "Clock Control" on page 234. Alternatively, the UART may be clocked from the internal precision oscillator (PIOSC), independent of the system clock selection. This will allow the UART clock to be programmed independently of the system clock PLL settings. See the **UARTCC** register for more details.

The 6-bit fractional number (that is to be loaded into the DIVFRAC bit field in the **UARTFBRD** register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8x or 16x the baud-rate (referred to as Baud8 and Baud16, depending on the setting of the HSE bit (bit 5) in **UARTCTL**). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during

receive operations. Note that the state of the HSE bit has no effect on clock generation in ISO 7816 smart card mode (when the SMART bit in the **UARTCTL** register is set).

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 1305), the **UARTIBRD** and **UARTFBRD** registers form an internal 30-bit register. This internal register is only updated when a write operation to **UARTLCRH** is performed, so any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- **UARTIBRD** write, **UARTFBRD** write, and **UARTLCRH** write
- **UARTFBRD** write, **UARTIBRD** write, and **UARTLCRH** write
- **UARTIBRD** write and **UARTLCRH** write
- **UARTFBRD** write and **UARTLCRH** write

### 19.3.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the **UARTLCRH** register. Data continues to be transmitted until there is no data left in the transmit FIFO. The BUSY bit in the **UART Flag (UARTFR)** register (see page 1299) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The BUSY bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the UnRx signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of Baud16 or fourth cycle of Baud8 depending on the setting of the HSE bit (bit 5) in **UARTCTL** (described in “Transmit/Receive Logic” on page 1283).

The start bit is valid and recognized if the UnRx signal is still low on the eighth cycle of Baud16 (HSE clear) or the fourth cycle of Baud 8 (HSE set), otherwise it is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of Baud16 or 8th cycle of Baud8 (that is, one bit period later) according to the programmed length of the data characters and value of the HSE bit in **UARTCTL**. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the **UARTLCRH** register.

Lastly, a valid stop bit is confirmed if the UnRx signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

### 19.3.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the UnTx and UnRx pins for the SIR protocol. These signals should be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before

data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW and driving the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal (1.63  $\mu$ s, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCTL** register (see page 1307).

Whether the device is in normal or low-power IrDA mode, a start bit is deemed valid if the decoder is still Low, one period of IrLPBaud16 after the Low was first detected. This enables a normal-mode UART to receive data from a low-power mode UART that can transmit pulses as small as 1.41  $\mu$ s. Thus, for both low-power and normal mode operation, the ILPDVSR field in the **UARTILPR** register must be programmed such that  $1.42 \text{ MHz} < F_{\text{IrLPBaud16}} < 2.12 \text{ MHz}$ , resulting in a low-power pulse duration of 1.41–2.11  $\mu$ s (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4  $\mu$ s are accepted as valid pulses.

Figure 19-3 on page 1285 shows the UART transmit and receive signals, with and without IrDA modulation.

**Figure 19-3. IrDA Data Modulation**

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10-ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

### 19.3.5 ISO 7816 Support

The UART offers basic support to allow communication with an ISO 7816 smartcard. When bit 3 (SMART) of the **UARTCTL** register is set, the UnTx signal is used as a bit clock, and the UnRx signal is used as the half-duplex communication line connected to the smartcard. A GPIO signal can be used to generate the reset signal to the smartcard. The remaining smartcard signals should be provided by the system design. The maximum clock rate in this mode is system clock / 16.

When using ISO 7816 mode, the **UARTLCRH** register must be set to transmit 8-bit words (WLEN bits 6:5 configured to 0x3) with EVEN parity (PEN set and EPS set). In this mode, the UART automatically uses 2 stop bits, and the STP2 bit of the **UARTLCRH** register is ignored.

If a parity error is detected during transmission, UnRx is pulled Low during the second stop bit. In this case, the UART aborts the transmission, flushes the transmit FIFO and discards any data it contains, and raises a parity error interrupt, allowing software to detect the problem and initiate retransmission of the affected data. Note that the UART does not support automatic retransmission in this case.

### 19.3.6 Modem Handshake Support

This section describes how to configure and use the modem flow control and status signals for a UART when connected as a DTE (data terminal equipment) or as a DCE (data communications equipment). In general, a modem is a DCE and a computing device that connects to a modem is the DTE.

#### 19.3.6.1 Signaling

The status signals provided by a UART differ based on whether the UART is used as a DTE or DCE. When used as a DTE, the modem flow control and status signals are defined as:

- $\overline{\text{UnCTS}}$  is Clear To Send
- $\overline{\text{UnDSR}}$  is Data Set Ready
- $\overline{\text{UnDCD}}$  is Data Carrier Detect
- $\overline{\text{UnRI}}$  is Ring Indicator
- $\overline{\text{UnRTS}}$  is Request To Send
- $\overline{\text{UnDTR}}$  is Data Terminal Ready

When used as a DCE, the modem flow control and status signals are defined as:

- $\overline{\text{UnCTS}}$  is Request To Send
- $\overline{\text{UnDSR}}$  is Data Terminal Ready
- $\overline{\text{UnRTS}}$  is Clear To Send
- $\overline{\text{UnDTR}}$  is Data Set Ready

Note that the support for DCE functions Data Carrier Detect and Ring Indicator are not provided. If these signals are required, their function can be emulated by using a general-purpose I/O signal and providing software support.

### 19.3.6.2 Flow Control

Flow control can be accomplished by either hardware or software. The following sections describe the different methods.

#### **Hardware Flow Control (RTS/CTS)**

Hardware flow control between two devices is accomplished by connecting the  $\overline{\text{RTS}}$  output to the Clear-To-Send input on the receiving device, and connecting the Request-To-Send output on the receiving device to the  $\overline{\text{CTS}}$  input.

The  $\overline{\text{CTS}}$  input controls the transmitter. The transmitter may only transmit data when the  $\overline{\text{CTS}}$  input is asserted. The  $\overline{\text{RTS}}$  output signal indicates the state of the receive FIFO.  $\overline{\text{CTS}}$  remains asserted until the preprogrammed watermark level is reached, indicating that the Receive FIFO has no space to store additional characters.

The **UARTCTL** register bits 15 (CTSEN) and 14 (RTSEN) specify the flow control mode as shown in Table 19-2 on page 1287.

**Table 19-2. Flow Control Mode**

| CTSEN | RTSEN | Description                            |
|-------|-------|----------------------------------------|
| 1     | 1     | RTS and CTS flow control enabled       |
| 1     | 0     | Only CTS flow control enabled          |
| 0     | 1     | Only RTS flow control enabled          |
| 0     | 0     | Both RTS and CTS flow control disabled |

Note that when RTSEN is 1, software cannot modify the  $\overline{\text{RTS}}$  output value through the **UARTCTL** register Request to Send (RTS) bit, and the status of the RTS bit should be ignored.

#### **Software Flow Control (Modem Status Interrupts)**

Software flow control between two devices is accomplished by using interrupts to indicate the status of the UART. Interrupts may be generated for the  $\overline{\text{DSR}}$ ,  $\overline{\text{DCD}}$ ,  $\overline{\text{CTS}}$ , and  $\overline{\text{RI}}$  signals using bits 3:0 of the **UARTIM** register, respectively. The raw and masked interrupt status may be checked using the **UARTRIS** and **UARTMIS** register. These interrupts may be cleared using the **UARTICR** register.

### 19.3.7 9-Bit UART Mode

The UART provides a 9-bit mode that is enabled with the 9BITEN bit in the **UART9BITADDR** register. This feature is useful in a multi-drop configuration of the UART where a single master connected to multiple slaves can communicate with a particular slave through its address or set of addresses along with a qualifier for an address byte. All the slaves check for the address qualifier in the place of the parity bit and, if set, then compare the byte received with the preprogrammed address. If the address matches, then it receives or sends further data. If the address does not match, it drops the address byte and any subsequent data bytes. If the UART is in 9-bit mode, then the receiver operates with no parity mode. The address can be predefined to match with the received byte and it can be configured with the **UART9BITADDR** register. The matching can be extended to a set of addresses using the address mask in the **UART9BITAMASK** register. By default, the **UART9BITAMASK** is 0xFF, meaning that only the specified address is matched.

When not finding a match, the rest of the data bytes with the 9th bit cleared are dropped. If a match is found, then an interrupt is generated to the NVIC for further action. The subsequent data bytes with the cleared 9th bit are stored in the FIFO. Software can mask this interrupt in case  $\mu$ DMA and/or FIFO operations are enabled for this instance and processor intervention is not required. All the

send transactions with 9-bit mode are data bytes and the 9th bit is cleared. Software can override the 9th bit to be set (to indicate address) by overriding the parity settings to sticky parity with odd parity enabled for a particular byte. To match the transmission time with correct parity settings, the address byte can be transmitted as a single then a burst transfer. The Transmit FIFO does not hold the address/data bit, hence software should take care of enabling the address bit appropriately.

### 19.3.8 FIFO Operation

The UART has two 16x8 FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 1294). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the FEN bit in **UARTLCRH** (page 1305).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 1299) and the **UART Receive Status (UARTRSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits), and the **UARTRSR** register shows overrun status via the OE bit. If the FIFOs are disabled, the empty and full flags are set according to the status of the 1-byte-deep holding registers.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 1311). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , and  $\frac{7}{8}$ . For example, if the  $\frac{1}{4}$  option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the  $\frac{1}{2}$  mark.

### 19.3.9 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error
- Parity Error
- Framing Error
- Receive Timeout
- Transmit (when condition defined in the TXIFLSEL bit in the **UARTIFLS** register is met, or if the EOT bit in **UARTCTL** is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the RXIFLSEL bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 1321).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 1313) by setting the corresponding IM bits. If interrupts are not used, the raw interrupt status is always visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 1317).

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by writing a 1 to the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 1325).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period when the HSE bit is clear or over a 64-bit period when the HSE bit is set. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

The receive interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the RXRIS bit is set. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the trigger level, or by clearing the interrupt by writing a 1 to the RXIC bit.
- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the RXRIS bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, or by clearing the interrupt by writing a 1 to the RXIC bit.

The transmit interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the TXRIS bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts will be generated. The transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger level, or by clearing the interrupt by writing a 1 to the TXIC bit.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the TXRIS bit is set. It is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt by writing a 1 to the TXIC bit.

### 19.3.10 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the LBE bit in the **UARTCTL** register (see page 1307). In loopback mode, data transmitted on the UnTx output is received on the UnRx input. Note that the LBE bit should be set before the UART is enabled.

### 19.3.11 DMA Operation

The UART provides an interface to the  $\mu$ DMA controller with separate channels for transmit and receive. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the **UARTIFLS** register. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending on how the DMA channel is configured.

To enable DMA operation for the receive channel, set the RXDMAE bit of the **DMA Control (UARTDMACTL)** register. To enable DMA operation for the transmit channel, set the TXDMAE bit of the **UARTDMACTL** register. The UART can also be configured to stop using DMA for the receive

channel if a receive error occurs. If the DMAERR bit of the **UARTDMACR** register is set and a receive error occurs, the DMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

When the  $\mu$ DMA is finished transferring data to the TX FIFO or from the RX FIFO, a dma\_done signal is sent to the UART to indicate completion. The dma\_done status is indicated through the DMATXRIS and DMARXIS bits of the **UARTRIS** register. An interrupt can be generated from these status bits by setting the DMATXIM and/or DMARXIM bits in the **UARTIM** register.

**Note:** The DMATXRIS bit can be used to indicate the  $\mu$ DMA's completion of data transfer to the TX FIFO. To indicate transfer completion from the UART's serializer, the end-of-transmission bit (EOT bit) should be enabled in the **UARTCTL** register. An interrupt can be generated on an end-of-transmission completion by setting the EOTIM bit of the **UARTIM** register.

See "Micro Direct Memory Access ( $\mu$ DMA)" on page 677 for more details about programming the  $\mu$ DMA controller.

## 19.4 Initialization and Configuration

To enable and initialize the UART, the following steps are necessary:

1. Enable the UART module using the **RCGCUART** register (see page 392).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 386). To find out which GPIO port to enable, refer to Table 29-5 on page 1887.
3. Set the GPIO AFSEL bits for the appropriate pins (see page 771). To determine which GPIOs to configure, see Table 29-4 on page 1873.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected (see page 773 and page 781).
5. Configure the PMcN fields in the **GPIOCTL** register to assign the UART signals to the appropriate pins (see page 788 and Table 29-5 on page 1887).

To use the UART, the peripheral clock must be enabled by setting the appropriate bit in the **RCGCUART** register (page 392). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (page 386) in the System Control module. To find out which GPIO port to enable, refer to Table 29-5 on page 1887.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz, and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity
- FIFOs disabled
- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), because the **UARTIBRD** and **UARTFBRD** registers must be written before the **UARTLCRH** register. Using the equation described in “Baud-Rate Generation” on page 1283, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the DIVINT field of the **UARTIBRD** register (see page 1303) should be set to 10 decimal or 0xA. The value to be loaded into the **UARTFBRD** register (see page 1304) is calculated by the equation:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the UARTEN bit in the **UARTCTL** register.
2. Write the integer portion of the BRD to the **UARTIBRD** register.
3. Write the fractional portion of the BRD to the **UARTFBRD** register.
4. Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
5. Configure the UART clock source by writing to the **UARTCC** register.
6. Optionally, configure the  $\mu$ DMA channel (see “Micro Direct Memory Access ( $\mu$ DMA)” on page 677) and enable the DMA option(s) in the **UARTDMACTL** register.
7. Enable the UART by setting the UARTEN bit in the **UARTCTL** register.

## 19.5 Register Map

Table 19-3 on page 1292 lists the UART registers. The offset listed is a hexadecimal increment to the register's address, relative to that UART's base address:

- UART0: 0x4000.C000
- UART1: 0x4000.D000
- UART2: 0x4000.E000
- UART3: 0x4000.F000
- UART4: 0x4001.0000
- UART5: 0x4001.1000
- UART6: 0x4001.2000
- UART7: 0x4001.3000

The UART module clock must be enabled before the registers can be programmed (see page 392). There must be a delay of 3 system clocks after the UART module clock is enabled before any UART module registers are accessed.

The UART must be disabled (see the UARTEN bit in the **UARTCTL** register on page 1307) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)

- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

**Table 19-3. UART Register Map**

| Offset | Name          | Type | Reset       | Description                       | See page |
|--------|---------------|------|-------------|-----------------------------------|----------|

## 19.6 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

**Register 1: UART Data (UARTDR), offset 0x000**

**Important:** This register is read-sensitive. See the register description for details.

This register is the data register (the interface to the FIFOs).

For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

**UART Data (UARTDR)**

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000

## Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared on reset.

#### Value Description

|   |                                                                       |
|---|-----------------------------------------------------------------------|
| 0 | No data has been lost due to a FIFO overrun.                          |
| 1 | New data was received when the FIFO was full, resulting in data loss. |

This bit is cleared by a write to **UARTECR**.

The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO.

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|-------------|
|-----------|------|------|-------|-------------|

|   |    |    |   |                  |
|---|----|----|---|------------------|
| 2 | BE | RO | 0 | UART Break Error |
|---|----|----|---|------------------|

| Value | Description |
|-------|-------------|
|-------|-------------|

|   |                                 |
|---|---------------------------------|
| 0 | No break condition has occurred |
|---|---------------------------------|

|   |                                                                                                                                                                                         |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits). |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

This bit is cleared to 0 by a write to **UARTECR**.

In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received.

|   |    |    |   |                   |
|---|----|----|---|-------------------|
| 1 | PE | RO | 0 | UART Parity Error |
|---|----|----|---|-------------------|

| Value | Description |
|-------|-------------|
|-------|-------------|

|   |                              |
|---|------------------------------|
| 0 | No parity error has occurred |
|---|------------------------------|

|   |                                                                                                                              |
|---|------------------------------------------------------------------------------------------------------------------------------|
| 1 | The parity of the received data character does not match the parity defined by bits 2 and 7 of the <b>UARTLCRH</b> register. |
|---|------------------------------------------------------------------------------------------------------------------------------|

This bit is cleared to 0 by a write to **UARTECR**.

|   |    |    |   |                    |
|---|----|----|---|--------------------|
| 0 | FE | RO | 0 | UART Framing Error |
|---|----|----|---|--------------------|

| Value | Description |
|-------|-------------|
|-------|-------------|

|   |                               |
|---|-------------------------------|
| 0 | No framing error has occurred |
|---|-------------------------------|

|   |                                                                                |
|---|--------------------------------------------------------------------------------|
| 1 | The received character does not have a valid stop bit (a valid stop bit is 1). |
|---|--------------------------------------------------------------------------------|

This bit is cleared to 0 by a write to **UARTECR**.

In FIFO mode, this error is associated with the character at the top of the FIFO.

### Register 3: UART Flag (UARTFR), offset 0x018

The **UARTFR** register is the flag register. After reset, the TXFF, RXFF, and BUSY bits are 0, and TXFE and RXFE bits are 1.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

#### UART Flag (UARTFR)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000

**Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020**

The **UARTILPR** register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset.

The internal IrLPBaud16 clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the IrLPBaud16 clock. The low-power divisor value is calculated as follows:

$$ILPDVSR = \text{SysClk} / F_{\text{IrLPBaud16}}$$

where  $F_{\text{IrLPBaud16}}$  is nominally 1.8432 MHz.

Because the IrLPBaud16 clock is used to sample transmitted data irrespective of mode, the ILPDVSR field must be programmed in both low power and normal mode, such that  $1.42 \text{ MHz} < F_{\text{IrLPBaud16}} < 2.12 \text{ MHz}$ , resulting in a low-power pulse duration of 1.41–2.11  $\mu\text{s}$  (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4  $\mu\text{s}$  are accepted as valid pulses.

**Note:** Zero is an illegal value. Programming a zero value results in no IrLPBaud16 pulses being generated.

## Register 7: UART Line Control (UARTLCRH), offset 0x02C

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

For the proper execution of the break command, software must set this bit for at least two frames (character periods).                                                                   |

## Register 8: UART Control (UARTCTL), offset 0x030

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set.

To enable the UART module, the UARTEN bit must be set. If software requires a configuration change in the module, the UARTEN bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

**Note:** The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by clearing bit 4 (FEN) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

**Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034**

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the TXRIS and RXRIS bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**UART Interrupt FIFO Level Select (UARTIFLS)**

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 UART3 base: 0x4000.F000  
 UART4 base: 0x4001.0000  
 UART5 base: 0x4001.1000  
 UART6 base: 0x4001.2000  
 UART7 base: 0x4001.3000  
 Offset 0x034  
 Type RW, reset 0x0000.0012

In this case, the setting of TXIFLSEL is ignored.                                                                                                                                                                                                                                                                                                                                             |       |             |     |                                  |     |                                  |     |                                            |     |                                  |     |                                  |         |          |

## Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

### UART Interrupt Mask (UARTIM)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 UART3 base: 0x4000.F000  
 UART4 base: 0x4001.0000  
 UART5 base: 0x4001.1000  
 UART6 base: 0x4001.2000  
 UART7 base: 0x4001.3000  
 Offset 0x038  
 Type RW, reset 0x0000.0000

**Register 12: UART Masked Interrupt Status (UARTMIS), offset 0x040**

The **UARTMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

**UART Masked Interrupt Status (UARTMIS)**

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 UART3 base: 0x4000.F000  
 UART4 base: 0x4001.0000  
 UART5 base: 0x4001.1000

**Register 13: UART Interrupt Clear (UARTICR), offset 0x044**

The **UARTICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt (both raw interrupt and masked interrupt, if enabled) is cleared. A write of 0 has no effect.

Note that bits [3:0] are only implemented on UART1. These bits are reserved on UART0 and UART2.

**UART Interrupt Clear (UARTICR)**

**Register 16: UART 9-Bit Self Address Mask (UART9BITAMASK), offset 0x0A8**

The **UART9BITAMASK** register is used to enable the address mask for 9-bit mode. The address bits are masked to create a set of addresses to be matched with the received address byte.

**Register 18: UART Clock Configuration (UARTCC), offset 0xFC8**

The **UARTCC** register controls the baud clock source for the UART module. For more information, see the section called “Peripheral Clock Sources” on page 238.

**Note:** If the PIOSC is used for the UART baud clock, the system clock frequency must be at least 9 MHz in Run mode.

**UART Clock Configuration (UARTCC)**

## 20 Quad Synchronous Serial Interface (QSSI)

The TM4C129DNCZAD microcontroller includes four Quad-Synchronous Serial Interface (QSSI) modules. All four of the modules support Advanced and Bi-SSI interfaces as well as a Quad-SSI enhancement to provide faster throughput of data. The QSSI module acts as a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, or Texas Instruments synchronous serial interfaces. The QSSI performs serial-to-parallel conversion on data received from a peripheral device. The transmit and receive paths are buffered with internal, independent FIFO memories allowing up to eight 16-bit values in Legacy mode and 8-bit values in Advanced, Bi-, and Quad-modes. The CPU can access data in these FIFOs as well as the QSSI's control and status information. A  $\mu$ DMA interface is also provided to allow the transmit and receive FIFOs to be programmed as source/destination addresses in the  $\mu$ DMA module.

The TM4C129DNCZAD QSSI modules have the following features:

- Four QSSI channels with Advanced, Bi- and Quad-SSI functionality
- Programmable interface operation for Freescale SPI or Texas Instruments synchronous serial interfaces in Legacy Mode. Support for Freescale interface in Bi- and Quad-SSI mode.
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when four or more entries are available to be written in the FIFO
  - Maskable  $\mu$ DMA interrupts for receive and transmit complete
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCCLK) can be used to generate baud clock.

### 20.1 Block Diagram

The following figure below shows a block diagram of an QSSI module with Advanced, Bi- and Quad-SSI.

Figure 20-1. QSSI Module with Advanced, Bi-SSI and Quad-SSI Support

20.2 Signal Description

The following table lists the external signals of the QSSI module and describes the function of each. The QSSI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The "Pin Mux/Pin Assignment" column in the following table lists the possible GPIO pin placements for the QSSI signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to choose the QSSI function. The number in

parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 788) to assign the QSSI signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 741. Note that for the QSSI module, when operating in Legacy Mode, SSInXDAT0 functions as SSInTX and SSInXDAT1 functions as SSInRX).

**Table 20-1. SSI Signals (212BGA)**

| Pin Name  | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                                                         |

## 20.3 Functional Description

The QSSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The QSSI also supports the  $\mu$ DMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the  $\mu$ DMA module.  $\mu$ DMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 1379).

### 20.3.1 Bit Rate Generation

The QSSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (SysClk). The clock is first divided by an even prescale value CPSDVSR from 2 to 254, which is programmed in the **SSI Clock Prescale (SSICPSR)** register (see page 1371). The clock is further divided by a value from 1 to 256, which is  $1 + \text{SCR}$ , where SCR is the value programmed in the **SSI Control 0 (SSICR0)** register (see page 1363).

The frequency of the output clock SSInClk is defined by:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

**Note:** SYSClk or ALTCLK is used as the source for the SSInClk depending on how the CS field in the **SSI Clock Configuration (SSICC)** register is configured. For master legacy mode, the SYSClk or ALTCLK must be at least two times faster than the SSInClk, with the restriction that SSInClk cannot be faster than 60 MHz. For slave mode, SYSClk or ALTCLK must be at least 12 times faster than the SSInClk. In slave legacy mode, the maximum frequency of SSInClk is 10 MHz.

See "Synchronous Serial Interface (SSI)" on page 1941 to view legacy SSI and QSSI timing parameters.

### 20.3.2 FIFO Operation

#### 20.3.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 1368), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to a legacy SSI serial conversion and transmission to the attached slave or master, respectively, through the SSInDAT0/SSInTX pin.

In slave mode, the legacy SSI transmits data each time the master initiates a transaction. If the transmit FIFO is empty and the master initiates, the slave transmits the 8th most recent value in the transmit FIFO. If less than 8 values have been written to the transmit FIFO since the SSI module clock was enabled using the Rn bit in the **RCGCSSI** register or if the QSSI is reset using the **SRSSI** register, then 0 is transmitted. Care should be taken to ensure that valid data is in the FIFO as needed. The QSSI can be configured to generate an interrupt or a  $\mu$ DMA request when the FIFO is empty.

**Note:** When operating in Legacy Mode, the QuadSSI's SSInXDAT0 signal functions as SSInTX.

### 20.3.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data using the legacy serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register. If the receive FIFO is full when the master or slave receives new data, the data is held off until the receive FIFO has space.

When configured as a master or slave, serial data received through the SSInDAT1/SSInRX pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

**Note:** When operating in Legacy Mode, the QSSI's SSInXDAT1 signal functions as SSInRX.

### 20.3.3 Advanced, Bi- and Quad- SSI Function

Bi-SSI uses two data pins, SSInXDAT0 and SSInXDAT1, that can be configured to receive or transmit data. In Quad-SSI mode, SSInXDAT0, SSInXDAT1, SSInXDAT2 and SSInXDAT3 allow four bits of data to be received or transmitted at once. Note that in bi- and quad-SSI data transfers are only half-duplex.

By programming the MODE bits in the **SSICR1** register, Advanced, Bi- or Quad- SSI can be enabled. A direction bit, DIR, is provided to program the direction of operation during a Bi- or Quad SSI-transaction. Since Bi- and Quad-SSI cannot be full duplex, the DIR bit defines whether or not the RX FIFO is disabled. In Advanced operation, if the QSSI module TX (write) mode is enabled, the RX FIFO is automatically prevented from receiving any data. When Advanced SSI is in RX (read) mode, it operates as a full-duplex interface.

In Bi- and Quad-SSI mode, because only 8-bit data is allowed, the DSS bit field must be programmed to 0x7 in the **SSICR0** register before transferring data to the Rx and TX FIFOs. For a data transmit, the 8-bit data packet is placed in a TX FIFO entry bits [7:0] and the mode of operation is inserted in the three most significant bits of the TX FIFO entry. The mode of operation bits [15:13] in the TX FIFO are used by the QSSI module for configuring the data on the proper pins. The following modes that may be placed on bits [15:13] of the FIFO entry are:

- Bi-SSI mode (0x1)
- Quad-SSI mode (0x2)
- Advanced SSI mode (0x3)

When data is first written to the TX FIFO, a SSInFss is asserted low indicating the start of a frame. At the end of transmission, bit 12 of the last data entry in the TX FIFO signifies whether a frame is ending. When the EOM bit is 1 it indicates a End of Message (EOM or STOP frame) and SSInFss is subsequently forced high. The EOM bit is cleared in the **SSICR1** register on the same clock that the write to TXFIFO is completed. An EOM bit value of 0 indicates no change in transmission. If TX FIFO is emptied and SSInFSS is still asserted low, it remains low but SSInCLK is not pulsed. Likewise, if SSInFss is high when the TX FIFO is empty, it remains high.

During a Bi-SSI transmit frame, data is shifted out by two bits and placed on the corresponding two SSInDATn pins. For a Quad-SSI transmit frame data is shifted out by four bits and placed on the corresponding four SSInDATn pins.

In Bi-, Quad- and Advanced SSI, the lower byte of the Rx FIFO contains received data. The upper byte contains no valid information.

**Note:** While the master is in Bi- or Quad-SSI mode, if the DSS bit in the **SSICR0** register is not set to 0x7, the QSSI module reverts to Legacy mode and behavior is not guaranteed.

The **SSICR1** register bits DIR and MODE are used to program what operation is needed for the next data bytes that are being loaded into the FIFO. Table 20-2 on page 1350 shows available modes of operation:

**Table 20-2. QSSI Transaction Encodings**

| DIR | MODE | Operation                                                                             |
|-----|------|---------------------------------------------------------------------------------------|
| X   | 0x0  | SSI Legacy operation supporting 4 to 16 data bits                                     |
| 0   | 0x1  | Transmit (TX) Bi-SSI with 8-bits of packet data                                       |
| 0   | 0x2  | Transmit (TX) Quad-SSI with 8-bits of packet data                                     |
| 0   | 0x3  | Transmit (TX) Advanced SSI mode with 8-bits of packet data and write RX FIFO disabled |
| 1   | 0x1  | Receive (RX) Bi-SSI with 8-bits of packet data                                        |
| 1   | 0x2  | Receive (RX) Quad-SSI with 8-bits of packet data                                      |
| 1   | 0x3  | Full duplex Advance SSI with 8-bits of packet data                                    |

**Note:** SP0 = 0 and SPH = 0 is the only frame structure allowed for Advanced, Bi- and Quad-mode.

Different transactions can follow one another in the FIFOs. The following transaction combinations are allowed:

- Legacy SSI mode (if configured for this mode, switching to any other alternate mode is not recommended)
- Advanced SSI mode followed by Bi-SSI mode
- Advanced SSI mode followed by Quad-SSI mode
- Advanced SSI mode followed by Bi-SSI mode followed by Advanced SSI mode
- Advanced SSI mode followed by Quad-SSI mode followed by Advanced SSI mode

Note that switching between Quad-SSI and Bi-SSI is not encouraged in a single transaction.

#### 20.3.4 SSInFSS Function

For enhanced modes of operation, the SSInFss signal can be programmed to assert low at the start of each byte transfer for one clock or the entire frame. This is configured by programming the FSSHLDFRM bit in the **SSICR1** register. The EOM bit is also provided to signify end of frame transmission. This bit is embedded in the TXFIFO entry for use at the interface to deassert SSInFss at the appropriate time. The FSSHLDFRM bit can also be used when operating in 8-bit Legacy SSI mode.

The functionality of the FSSHLDFRM bit for both Legacy SSI mode and the enhanced modes are as follows:

**Table 20-3. SSInFss Functionality**

| Mode                       | FSSHLDFRM | Description                                                                                                                                                                                                                                                                  |
|----------------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Legacy Mode                | 0         | For Freescale format, with SPH = 0, the SSInFss signal is asserted low between continuous transfers. For SPH = 1, the SSInFss signal is deasserted (high) between continuous transfers.<br>For TI format, the SSInFss signal is deasserted (high) after every data transfer. |
|                            | 1         | For Freescale format with any SPH value, the SSInFss signal is forced high between continuous transfers; it is asserted low when there is available data in the Tx FIFO; otherwise it is forced high to be ready for a new frame                                             |
| Advanced/Bi-/Quad-SSI Mode | 0         | SSInFss is asserted low after every byte of data                                                                                                                                                                                                                             |
|                            | 1         | New data written to the TX FIFO notifies SSInFss to assert low until the Tx FIFO is empty.                                                                                                                                                                                   |

### 20.3.5 High Speed Clock Operation

In master mode, QSSI module can enable a high speed clock by setting the HSCLKEN bit in the **SSI Control 1 (SSICR1)** register. In this mode of operation, SSInCLK from the QSSI master operation is reflected back as a loopback clock, HSPEEDCLK, to the QSSI module. This allows faster timing since the logic can be used to adjust clock to external data relationships. HSPEEDCLK captures RX data in a separate register. This allows the time between the clock as seen by a remote device and the internal clock to match more closely.

Receive data is captured in a separate register sampled on loop-back clock (HSPEEDCLK) and the RX FIFO write control registered on HSPEEDCLK. If the HSCKEN = 1, the corresponding shift register and FIFO write enable will be selected for use. This supports faster QSSI master speed.

**Note:** For proper functionality of high speed mode, the HSCLKEN bit in the **SSICR1** register should be set before any SSI data transfer or after applying a reset to the QSSI module. In addition, the SSE bit must be set to 0x1 before the HSCLKEN bit is set.

### 20.3.6 Interrupts

The QSSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service (when the transmit FIFO is half full or less)
- Receive FIFO service (when the receive FIFO is half full or more)
- Receive FIFO time-out
- Receive FIFO overrun
- End of transmission
- Receive DMA transfer complete
- Transmit DMA transfer complete

All of the interrupt events are ORed together before being sent to the interrupt controller, so the QSSI generates a single interrupt request to the controller regardless of the number of active interrupts. Each of the seven individual maskable interrupts can be masked by clearing the appropriate bit in the **SSI Interrupt Mask (SSIIM)** register (see page 1372). Setting the appropriate mask bit enables the interrupt.

The individual outputs, along with a combined interrupt output, allow use of either a global interrupt service routine or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 1374 and page 1376, respectively).

The RX FIFO has an associated time-out counter which starts to down count at the same time the RX FIFO is flagged as not empty by the RNE bit in the **SSISR** register. The counter is reset any time a new or next byte is written to the RX FIFO, thus the counter will continue to count down to zero unless there is new activity. The time-out period is 32 periods based on the period of SSInClk. When the counter reaches zero, a time-out interrupt bit, RTRIS, is set in the **SSIRIS** register. The time-out interrupt can be cleared by writing a 1 to the RTIC bit of the **SSI Interrupt Clear (SSIC)** register or by emptying the RX FIFO. If the interrupt is cleared and there is residual data left in the RX FIFO or new data entries have been written, the timer count down initiates and the interrupt will be reasserted after 32 periods have been counted.

The End-of-Transmission (EOT) interrupt indicates that the data has been transmitted completely and is only valid for Master mode devices/operations. This interrupt can be used to indicate when it is safe to turn off the QSSI module clock or enter sleep mode. In addition, because transmitted data and received data complete at exactly the same time, the interrupt can also indicate that read data is ready immediately, without waiting for the receive FIFO time-out period to complete.

**Note:** In Freescale SPI mode only, a condition can be created where an EOT interrupt is generated for every byte transferred even if the FIFO is full. If the EOT bit has been set to 0 in an integrated slave QSSI and the  $\mu$ DMA has been configured to transfer data from this QSSI to a Master QSSI on the device using external loopback, an EOT interrupt is generated by the QSSI slave for every byte even if the FIFO is full.

### 20.3.7 Frame Formats

Each data frame is between 4 and 16 bits long in Legacy mode and 8-bits in Advanced/Bi-/Quad-SSI mode and is transmitted starting with the MSB. There are two basic frame types that can be selected by programming the FRF bit in the **SSICR0** register:

- Texas Instruments synchronous serial
- Freescale SPI

**Note:** Advanced, Bi- and Quad-SSI modules only supports Freescale mode when SPH=0; SP0=0 and DDS=0x8 in the **SSI Control 0 (SSICR0)** register.

For both formats, the serial clock (SSInClk) is held inactive while the QSSI is idle, and SSInClk transitions at the programmed frequency only during active transmission or reception of data. The idle state of SSInClk is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI frame format, the serial frame (SSInFss) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the SSInFss pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the QSSI and the off-chip slave device drive their output data on the rising edge of SSInClk and latch data from the other device on the falling edge.

The following table gives a synopsis of the features supported in each frame format when operating in Legacy Mode:

**Table 20-4. Legacy Mode TI, Freescale SPI Frame Format Features**

| Feature                            | TI Mode                  | Freescale SPI Mode                                                           |
|------------------------------------|--------------------------|------------------------------------------------------------------------------|
| Frame Hold                         | Not Available            | Available                                                                    |
| High Speed (Master RX Only)        | Not Available            | Available                                                                    |
| SPO/SPH Configuration              | Not Available            | Available and can be used in combination with Frame Hold and High Speed Mode |
| Frequency (system clock : SSInCLK) | Master 1:2<br>Slave 1:12 | Master 1:2<br>Slave 1:12                                                     |

For Advanced, Bi- and Quad-SSI modes using the Freescale SPI Format or the Bi- and Quad-SSI modes using the TI format, the following features are supported:

- Frame Hold
- High Speed (Master RX Only)
- SPO/SPH Configuration with SP0=0 and SPH=0 only allowed
- Frequency (system clock : SSInCLK):
  - Master 1:2
  - Slave 1:12

### 20.3.7.1 Texas Instruments Synchronous Serial Frame Format

Figure 20-2 on page 1353 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

**Figure 20-2. TI Synchronous Serial Frame Format (Single Transfer)**

In this mode, SSInClk and SSInFss are forced Low, and the transmit data line SSInDAT0/SSInTX is tristated whenever the QSSI is idle. Once the bottom entry of the transmit FIFO contains data, SSInFss is pulsed High for one SSInClk period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of SSInClk, the MSB of the 4 to 16-bit data frame is shifted out on the SSInDAT0/SSInTX pin. Likewise, the MSB of the received data is shifted onto the SSInDAT1/SSInRX pin by the off-chip serial slave device.

Both the QSSI and the off-chip serial slave device then clock each data bit into their serial shifter on each falling edge of SSInClk. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of SSInClk after the LSB has been latched.

Figure 20-3 on page 1354 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

**Figure 20-3. TI Synchronous Serial Frame Format (Continuous Transfer)**

### 20.3.7.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the SSInFss signal behaves as a slave select. If operating in Legacy Mode and using the Freescale SPI Frame Format, the inactive state and phase of the SSInClk signal are programmable through the SP0 and SPH bits in the **SSICR0** control register. If operating in Advanced/Bi-/Quad-SSI mode, the SP0 and SPH bits must be programmed to 0.

#### **SP0 Clock Polarity Bit**

When the SP0 clock polarity control bit is clear, it produces a steady state Low value on the SSInClk pin. If the SP0 bit is set, a steady state High value is placed on the SSInClk pin when data is not being transferred.

#### **SPH Phase Control Bit**

The SPH phase control bit selects the clock edge that captures data and allows it to change state. The state of this bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the SPH phase control bit is clear, data is captured on the first clock edge transition. If the SPH bit is set, data is captured on the second clock edge transition.

### 20.3.7.3 Freescale SPI Frame Format with SP0=0 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SP0=0 and SPH=0 are shown in Figure 20-4 on page 1355 and Figure 20-5 on page 1355.

**Note:** This is the only Freescale SPI frame format configuration that can be used when operating in Advanced/Bi-/Quad-SSI mode.

**Figure 20-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0**

**Note:** Q is undefined.

**Figure 20-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0**

In this configuration, during idle periods:

- SSInClk is forced Low
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is arbitrarily forced Low
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low, causing slave data to be enabled onto the SSInDAT1/SSInRX input line of the master. The master SSInDAT0/SSInTX output pad is enabled.

One half SSInClk period later, valid master data is transferred to the SSInDAT0/SSInTX pin. Once both the master and slave data have been set, the SSInClk master clock pin goes High after one additional half SSInClk period.

The data is now captured on the rising and propagated on the falling edges of the SSInClk signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the SSInFss line is returned to its idle High state one SSInClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSInFss signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the SSInFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSInFss pin is returned to its idle state one SSInClk period after the last bit has been captured.

#### 20.3.7.4 Freescale SPI Frame Format with SPO=0 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=0 and SPH=1 is shown in Figure 20-6 on page 1356, which covers both single and continuous transfers.

**Note:** This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

**Figure 20-6. Freescale SPI Frame Format with SPO=0 and SPH=1**

**Note:** Q is undefined.

In this configuration, during idle periods:

- SSInClk is forced Low
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is arbitrarily forced Low
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low. The master SSInDAT0/SSInTX output is enabled. After an additional one-half SSInClk period, both master and slave valid data are enabled onto their respective transmission lines. At the same time, the SSInClk is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the SSInClk signal.

In the case of a single word transfer, after all bits have been transferred, the SSInFss line is returned to its idle High state one SSInClk period after the last bit has been captured.

For continuous back-to-back transfers, the SSInFss pin is held Low between successive data words, and termination is the same as that of the single word transfer.

### 20.3.7.5 Freescale SPI Frame Format with SPO=1 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=1 and SPH=0 are shown in Figure 20-7 on page 1357 and Figure 20-8 on page 1357.

**Note:** This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

**Figure 20-7. Freescale SPI Frame Format (Single Transfer) with SPO=1 and SPH=0**

**Note:** Q is undefined.

**Figure 20-8. Freescale SPI Frame Format (Continuous Transfer) with SPO=1 and SPH=0**

In this configuration, during idle periods:

- SSInClk is forced High
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is arbitrarily forced Low
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low, causing slave data to be immediately transferred onto the SSInDAT1/SSInRX line of the master. The master SSInDAT0/SSInTX output pad is enabled.

One-half period later, valid master data is transferred to the SSInDAT0/SSInTX line. Once both the master and slave data have been set, the SSInClk master clock pin becomes Low after one additional half SSInClk period, meaning that data is captured on the falling edges and propagated on the rising edges of the SSInClk signal.

In the case of a single word transmission, after all bits of the data word are transferred, the SSInFss line is returned to its idle High state one SSInClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSInFss signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the SSInFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSInFss pin is returned to its idle state one SSInClk period after the last bit has been captured.

### 20.3.7.6 Freescale SPI Frame Format with SPO=1 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=1 and SPH=1 is shown in Figure 20-9 on page 1358, which covers both single and continuous transfers.

**Note:** This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

**Figure 20-9. Freescale SPI Frame Format with SPO=1 and SPH=1**

**Note:** Q is undefined.

In this configuration, during idle periods:

- SSInClk is forced High
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is arbitrarily forced Low
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low. The master SSInDAT0/SSInTX output pad is enabled. After an additional one-half SSInClk period, both master and slave data are enabled onto their respective transmission lines. At the same time, SSInClk is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SSInClk signal.

After all bits have been transferred, in the case of a single word transmission, the SSInFss line is returned to its idle high state one SSInClk period after the last bit has been captured.

For continuous back-to-back transmissions, the SSInFss pin remains in its active Low state until the final bit of the last word has been captured and then returns to its idle state as described above.

For continuous back-to-back transfers, the SSInFss pin is held Low between successive data words and termination is the same as that of the single word transfer.

### 20.3.8 DMA Operation

The QSSI peripheral provides an interface to the  $\mu$ DMA controller with separate channels for transmit and receive. The  $\mu$ DMA operation of the QSSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When  $\mu$ DMA operation is enabled, the QSSI asserts a  $\mu$ DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever at least one empty location is in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst  $\mu$ DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending how the  $\mu$ DMA channel is configured. To enable  $\mu$ DMA operation for the receive channel, the RXDMAE bit of the **DMA Control (SSIDMACTL)** register should be set. To enable  $\mu$ DMA operation for the transmit channel, the TXDMAE bit of **SSIDMACTL** should be set. If the  $\mu$ DMA is enabled and has completed a data transfer from the Tx FIFO, the DMATXRIS bit is set in the **SSIRIS** register. If a data transfer by the  $\mu$ DMA from the Rx FIFO completes, the DMARXRIS bit is set. The EOT bit in the **SSIRIS** register is also provided to indicate when the Tx FIFO is empty and the last bit has been transmitted out of the serializer.

See “Micro Direct Memory Access ( $\mu$ DMA)” on page 677 for more details about programming the  $\mu$ DMA controller.

## 20.4 Initialization and Configuration

To enable and initialize the QSSI, the following steps are necessary:

1. Enable the QSSI module using the **RCGCSSI** register (see page 394).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 386). To find out which GPIO port to enable, refer to Table 29-5 on page 1887.
3. Set the GPIO AFSEL bits for the appropriate pins (see page 771). To determine which GPIOs to configure, see Table 29-4 on page 1873.
4. Configure the PMCN fields in the **GPIOCTL** register to assign the QSSI signals to the appropriate pins. See page 788 and Table 29-5 on page 1887.
5. Program the **GPIODEN** register to enable the pin's digital function. In addition, the drive strength, drain select and pull-up/pull-down functions must be configured. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 741 for more information.

**Note:** Pull-ups can be used to avoid unnecessary toggles on the QSSI pins, which can take the slave to a wrong state. In addition, if the SSIClk signal is programmed to steady state high through the SP0 bit in the SSICR0 register, then software must also configure the GPIO port pin corresponding to the SSInClk signal as a pull-up in the **GPIO Pull-Up Select (GPIOPUR)** register, GPIO offset 0x510.

For each of the frame formats, the QSSI is configured using the following steps:

1. If initializing out of reset, ensure that the SSE bit in the **SSICR1** register is clear before making any configuration changes. Otherwise, configuration changes for Advanced SSI can be made while the SSE bit is set.
2. Select whether the QSSI is a master or slave:
  - a. For master operations, set the **SSICR1** register to 0x0000.0000.
  - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
  - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the QSSI clock source by writing to the **SSICC** register.
4. Configure the clock prescale divisor by writing the **SSICPSR** register.
5. Write the **SSICR0** register with the following configuration:
  - Serial clock rate (SCR)
  - Desired clock phase/polarity, if using Freescale SPI mode (SPH and SP0)
  - The protocol mode: Freescale SPI or TI SSF
  - The data size (DSS)
6. Optionally, configure the  $\mu$ DMA channel (see “Micro Direct Memory Access ( $\mu$ DMA)” on page 677) and enable the DMA option(s) in the **SSIDMACTL** register.
7. If this is the first initialization out of reset, enable the QSSI by setting the SSE bit in the **SSICR1** register.

As an example, assume the QSSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (SPO=1, SPH=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$\begin{aligned}\text{SSInClk} &= \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR})) \\ 1 \times 10^6 &= 20 \times 10^6 / (\text{CPSDVSR} * (1 + \text{SCR}))\end{aligned}$$

In this case, if CPSDVSR=0x2, SCR must be 0x9.

The configuration sequence would be as follows:

1. Ensure that the SSE bit in the **SSICR1** register is clear.
2. Write the **SSICR1** register with a value of 0x0000.0000.
3. Write the **SSICPSR** register with a value of 0x0000.0002.
4. Write the **SSICR0** register with a value of 0x0000.09C7.
5. The QSSI is then enabled by setting the SSE bit in the **SSICR1** register.

#### 20.4.1 Enhanced Mode Configuration

If the QSSI module supports the Advanced/Bi-/Quad features, then these modes can be enabled after initializing the QSSI module. Below is an example of configuring the QSSI to transmit two data bytes in Advanced SSI mode followed by 2 bytes in Bi-SSI mode:

1. Set the MODE bit to 0x3, and the FSSHLDPM bit to 1 in the **SSICR1** register. To operate in the master mode, program the MS bit to 0. Program the remaining bits in the **SSICR0** and **SSICR1** register to relevant values.
2. Write one data byte to the TX FIFO; set the EOM bit to 1 and write the second data byte to the Tx FIFO.
3. Set the MODE bit to 0x1 and the FSSHLDPM bit to 1 in the **SSICR1** register. To operate in the master mode, program the MS bit to 0. Program the remaining bits in the **SSICR0** and **SSICR1** register to relevant values.
4. Fill the Tx FIFO with one data byte.
5. Set the EOM bit in the **SSICR1** register.
6. Fill the Tx FIFO with one data byte.

## 20.5 Register Map

Table 20-5 on page 1361 lists the QSSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that QSSI module's base address:

- QSSI0: 0x4000.8000
- QSSI1: 0x4000.9000
- QSSI2: 0x4000.A000
- QSSI3: 0x4000.B000

Note that the QSSI module clock must be enabled before the registers can be programmed (see page 394). The Rn bit of the **PRSSI** register must be read as 0x1 before any QSSI module registers are accessed.

**Table 20-5. SSI Register Map**

| Offset | Name   | Type | Reset       | Description    | See page |
|--------|--------|------|-------------|----------------|----------|
| 0x000  | SSICR0 | RW   | 0x0000.0000 | QSSI Control 0 | 1363     |

Table 20-5. SSI Register Map (*continued*)

| Offset | Name         | Type | Reset       | Description                      | See page |
|--------|--------------|------|-------------|----------------------------------|----------|
| 0x004  | SSICR1       | RW   | 0x0000.0000 | QSSI Control 1                   | 1365     |
| 0x008  | SSIDR        | RW   | 0x0000.0000 | QSSI Data                        | 1368     |

## 20.6 Register Descriptions

The remainder of this section lists and describes the QSSI registers, in numerical order by address offset.

**Register 1: QSSI Control 0 (SSICR0), offset 0x000**

The **SSICR0** register contains bit fields that control various functions within the QSSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

**QSSI Control 0 (SSICR0)**

QSSI0 base: 0x4000.8000  
 QSSI1 base: 0x4000.9000  
 QSSI2 base: 0x4000.A000  
 QSSI3 base: 0x4000.B000  
 Offset 0x000  
 Type RW, reset 0x0000.0000

| Bit/Field | Name                                                                                       | Type | Reset  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |             |   |                                                        |   |                                                                                            |
|-----------|--------------------------------------------------------------------------------------------|------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------------|---|--------------------------------------------------------|---|--------------------------------------------------------------------------------------------|
| 31:16     | reserved                                                                                   | RO   | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                                                                                                                                                                                                      |       |             |   |                                                        |   |                                                                                            |
| 15:8      | SCR                                                                                        | RW   | 0x00   | <p>QSSI Serial Clock Rate</p> <p>This bit field is used to generate the transmit and receive bit rate of the QSSI. The bit rate is:<br/><math>BR = SysClk / (CPSDVSR * (1 + SCR))</math></p> <p>where CPSDVSR is an even value from 2-254 programmed in the <b>SSICPSR</b> register, and SCR is a value from 0-255.</p>                                                                                                                                                                                                                                                            |       |             |   |                                                        |   |                                                                                            |
| 7         | SPH                                                                                        | RW   | 0      | <p>QSSI Serial Clock Phase</p> <p>This bit is only applicable to the Freescale SPI Format.</p> <p>The SPH control bit selects the clock edge that captures data and allows it to change state. This bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Data is captured on the first clock edge transition.</td></tr><tr><td>1</td><td>Data is captured on the second clock edge transition.</td></tr></table> | Value | Description | 0 | Data is captured on the first clock edge transition.   | 1 | Data is captured on the second clock edge transition.                                      |

## Register 2: QSSI Control 1 (SSICR1), offset 0x004

The **SSICR1** register contains bit fields that control various functions within the QSSI module. Master and slave mode functionality is controlled by this register.

### QSSI Control 1 (SSICR1)

QSSI0 base: 0x4000.8000  
 QSSI1 base: 0x4000.9000  
 QSSI2 base: 0x4000.A000  
 QSSI3 base: 0x4000.B000  
 Offset 0x004  
 Type RW, reset 0x0000.0000

**Register 3: QSSI Data (SSIDR), offset 0x008**

**Important:** This register is read-sensitive. See the register description for details.

The **SSIDR** register is 16-bits wide. When the **SSIDR** register is read, the entry in the receive FIFO that is pointed to by the current FIFO read pointer is accessed. When a data value is removed by the QSSI receive logic from the incoming data frame, it is placed into the entry in the receive FIFO pointed to by the current FIFO write pointer.

When the **SSIDR** register is written to, the entry in the transmit FIFO that is pointed to by the write pointer is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. Each data value is loaded into the transmit serial shifter, then serially shifted out onto the SSInDAT0/SSInTX pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

## Register 5: QSSI Clock Prescale (SSICPSR), offset 0x010

The **SSICPSR** register specifies the division factor which is used to derive the SSInClk from the system clock. The clock is further divided by a value from 1 to 256, which is 1 + SCR. SCR is programmed in the **SSICR0** register. The frequency of the SSInClk is defined by:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

### QSSI Clock Prescale (SSICPSR)

**Register 6: QSSI Interrupt Mask (SSIIM), offset 0x014**

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared on reset.

On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit clears the mask, enabling the interrupt to be sent to the interrupt controller. Clearing a bit sets the corresponding mask, preventing the interrupt from being signaled to the controller.

**Register 9: QSSI Interrupt Clear (SSIICR), offset 0x020**

The **SSIICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

**QSSI Interrupt Clear (SSIICR)**

QSSI0 base: 0x4000.8000
