FL7732
Single-Stage PFC Primary-Side-Regulation Offline LED Driver

Features
- Cost-Effective Solution: No Input Bulk Capacitor or Feedback Circuitry
- Power Factor Correction
- Accurate Constant-Current (CC) Control, Independent Online Voltage, Output Voltage, and Magnetizing Inductance Variation
- Linear Frequency Control Improves Efficiency and Simplifies Design
- Open-LED Protection
- Short-LED Protection
- Cycle-by-Cycle Current Limiting
- Over-Temperature Protection with Auto Restart
- Low Startup Current: 20 μA
- Low Operating Current: 5 mA
- \( V_{DD} \) Under-Voltage Lockout (UVLO)
- Gate Output Maximum Voltage Clamped at 18 V
- SOP-8 Package
- Application Voltage Range: 80 VAC ~ 308 VAC

Description
This highly integrated PWM controller provides several features to enhance the performance of low-power flyback converters. The proprietary topology, TRUECURRENT® enables simplified circuit design for LED lighting applications.

By using single-stage topology with primary-side regulation, a LED lighting board can be implemented with few external components and minimized cost. No input bulk capacitor or feedback circuitry is required. To implement good power factor and low THD, constant on-time control is utilized with an external capacitor connected to the COMI pin.

Precise constant-current control regulates accurate output current versus changes in input voltage and output voltage. The operating frequency is proportionally adjusted by the output voltage to guarantee DCM operation with higher efficiency and simpler design.

FL7732 provides open-LED, short-LED, and over-temperature protection features. The current limit level is automatically reduced to minimize output current and protect external components in a short-LED condition.

The FL7732 controller is available in an 8-pin Small-Outline Package (SOP).

Applications
- LED Lighting System

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Functional Description

FL7732 is AC-DC PWM controller for LED lighting applications. TRUECURRENT® techniques regulate accurate LED current independent of input voltage, output voltage, and magnetizing inductance variations. The linear frequency control in the oscillator reduces conduction loss and maintains DCM operation in the wide range of output voltage, which implements high power factor correction in a single-stage flyback topology. A variety of protections, such as short/open-LED protection, over-temperature protection, and cycle-by-cycle current limitation stabilize system operation and protect external components.

Startup

Powering at startup is slow due to the low feedback loop bandwidth in PFC converter. To boost powering during startup, an internal oscillator counts 12 ms to define Startup Mode. During Startup Mode, turn-on time is determined by Current-Mode control with a 0.2 V CS voltage limit and transconductance becomes 14 times larger, as shown in Figure 15. After startup, turn-on time is controlled by Voltage Mode using COMI voltage and error amplifier transconductance is reduced to 85 μmho.

Figure 15. Startup Sequence

Constant-Current Regulation

The output current can be estimated using the peak drain current and inductor current discharge time since output current is same as the average of the diode current in steady state. The peak value of the drain current is determined by the CS pin and the inductor discharge time (t DIS) is sensed by t DIS detector. By using three points of information (peak drain current, inductor discharging time, and operating switching period); TRUECURRENT® calculation block estimates output current. The output of the calculation is compared with an internal precise reference to generate an error voltage (V COMI), which determines turn-on time in Voltage-Mode control. With Fairchild’s innovative TRUECURRENT® technique, constant-current output can be precisely controlled.

PFC and THD

In a conventional boost converter, Boundary Conduction Mode (BCM) is generally used to keep input current in-phase with input voltage for PF and THD. In flyback/buck boost topology, constant turn-on time and constant frequency in Discontinuous Conduction Mode (DCM) can implement high PF and low THD, as shown in Figure 16. Constant turn-on time is maintained by the internal error amplifier and a large external capacitor (typically over 1 μF) at the COMI pin. Constant frequency and DCM operation are managed by linear frequency control.

Figure 16. Input Current and Switching

Linear Frequency Control

As mentioned above, DCM should be guaranteed for high power factor in flyback topology. To maintain DCM across the wide range of output voltage, frequency is linearly adjusted by output voltage in linear frequency control. Output voltage is detected by the auxiliary winding and the resistive divider connected to the VS pin, as shown in Figure 17.

Figure 17. Linear Frequency Control
When output voltage decreases, secondary diode conduction time is increased and the linear frequency control lengthens the switching period, which retains DCM operation in the wide output voltage range, as shown in Figure 18. The frequency control lowers the primary rms current with better power efficiency in the full-load condition.

Figure 18. Primary and Secondary Current

BCM Control
The end of secondary diode conduction time is possibly over a switching period set by linear frequency control. In this case, FL7732 doesn’t allow CCM and the operation mode changes from DCM to BCM. Therefore, magnetizing inductance can be largely designed to add BCM for better efficiency if PF and THD meet specification with enough margin.

Short-LED Protection
In case of a short-LED condition, the switching MOSFET and secondary diode are stressed by the high powering current. However, FL7732 changes the OCP level in a short-LED condition. When \( V_S \) voltage is lower than 0.4 V, OCP level becomes 0.2 V from 0.7 V, as shown in Figure 19, so powering is limited and external components current stress is reduced.

Figure 19. Internal OCP Block

Open-LED Protection
FL7732 protects external components, such as diode and capacitor, at secondary side in open-LED condition. During switch-off, the \( V_{DD} \) capacitor is charged up to the auxiliary winding voltage, which is applied as the reflected output voltage. Because the \( V_{DD} \) voltage has output voltage information, the internal voltage comparator on the \( V_{DD} \) pin can trigger output Over-Voltage Protection (OVP), as shown in Figure 21. When at least one LED is open-circuited, output load impedance becomes very high and output capacitor is quickly charged up to \( V_{OVP} \times N_S / N_A \). Then switching is shut down and the \( V_{DD} \) block goes into Hiccup Mode until the open-LED condition is removed, as shown in Figure 22.

Figure 20 shows operational waveforms in short-LED condition. Output voltage is quickly lowered to 0V right after a short-LED event. Then the reflected auxiliary voltage is also 0 V, making \( V_S \) less than 0.4 V. 0.2 V OCP level limits primary-side current and \( V_{DD} \) hiccups up and down between UVLO hysteresis.

Figure 20. Waveforms in Short-LED Condition

Figure 21. Waveforms in Open-LED Condition

Figure 22. Waveforms in Open-LED Condition
Under-Voltage Lockout (UVLO)

The turn-on and turn-off thresholds are fixed internally at 16 V and 7.5 V, respectively. During startup, the \( V_{DD} \) capacitor must be charged to 16 V through the startup resistor to enable the FL7732. The \( V_{DD} \) capacitor continues to supply \( V_{DD} \) until power can be delivered from the auxiliary winding of the main transformer. \( V_{DD} \) must not drop below 7.5 V during this startup process. This UVLO hysteresis window ensures that the \( V_{DD} \) capacitor is adequate to supply \( V_{DD} \) during startup.

Over-Temperature Protection (OTP)

The FL7732 has a built-in temperature-sensing circuit to shut down PWM output if the junction temperature exceeds 150°C. While PWM output is shut down, the \( V_{DD} \) voltage gradually drops to the UVLO voltage. Some of the internal circuits are shut down and \( V_{DD} \) gradually starts increasing again. When \( V_{DD} \) reaches 16 V, all the internal circuits start operating. If the junction temperature is still higher than 140°C, the PWM controller is shut down immediately.

**Disclaimer**
Fairchild Semiconductor reserves the right to make changes without further notice to any products herein to improve reliability, function, or design. Fairchild does not assume any liability arising out of the application or use of any product or circuit described herein; neither does it convey any license under its patent rights, nor the rights of others. These specifications do not expand the terms of Fairchild’s worldwide terms and conditions, specifically the warranty therein, which covers these products.

**Life Support Policy**
Fairchild’s products are not authorized for use as critical components in life support devices or systems without the express written approval of Fairchild Semiconductor Corporation.

As used herein:
1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body or (b) support or sustain life, and (c) whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component in any component of a life support device, or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

**Anti-Counterfeiting Policy**
Fairchild Semiconductor Corporation’s Anti-Counterfeiting Policy is also stated on our external website, www.fairchilsemi.com, under Sales Support. Counterfeiting of semiconductor parts is a growing problem in the industry. All manufacturers of semiconductor products are experiencing counterfeiting of their parts. Customers who inadvertently purchase counterfeit parts experience many problems such as loss of brand reputation, substandard performance, failed applications, and increased cost of production and manufacturing delays. Fairchild is taking strong measures to protect our business, and we are thoroughly investigating the proliferation of counterfeit parts.
