CLC1001
Ultra-Low Noise Amplifier

General Description

The CLC1001 is a high-performance, voltage feedback amplifier with ultra-low input voltage noise, 0.6nV/√Hz. The CLC1001 provides 2.1GHz gain bandwidth product and 410V/µs slew rate making it well suited for high-speed data acquisition systems requiring high levels of sensitivity and signal integrity. This high-performance amplifier also offers low input offset voltage.

The CLC1001 is designed to operate from 4V to 12V supplies. It consumes only 12.5mA of supply current per channel and offers a power saving disable pin that disables the amplifier and decreases the supply current to below 225µA. The CLC1001 amplifier operates over the extended temperature range of -40°C to +125°C.

If a lower minimum stable gain is required, the CLC1002 offers a minimum stable gain of 5.

FEATURES

- 0.6nV/√Hz input voltage noise
- 1mV maximum input offset voltage
- 2.1GHz gain bandwidth product
- Minimum stable gain of 10
- 410V/µs slew rate
- 130mA output current
- -40°C to +125°C operating temperature range
- Fully specified at 5 and ±5V supplies
- CLC1001: ROHS compliant TSOT-6, SOIC-8 package options

APPLICATIONS

- Transimpedance amplifiers
- Pre-amplifier
- Low noise signal processing
- Medical instrumentation
- Probe equipment
- Test equipment
- Ultrasound channel amplifier

Absolute Maximum Ratings

Stresses beyond the limits listed below may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

V_S .... 0V to +14V

V_{IN} .... $-V_S$ - 0.5V to $+V_S$ +0.5V

Operating Conditions

Supply Voltage Range ....4 to 12V

Operating Temperature Range ....-40°C to 125°C

Junction Temperature .... 150°C

Storage Temperature Range...................................-65°C to 150°C

Lead Temperature (Soldering, 10s) ....260°C

Package Thermal Resistance

θ_{JA} (TSOT-6)...192°C/W

θ_{JA} (SOIC-8) ....150°C/W

Package thermal resistance (θ_{JA}), JEDEC standard, multi-layer test boards, still air.

ESD Protection

CLC1001 (HBM) 2kV

ESD Rating for HBM (Human Body Model).

Electrical Characteristics at +5V

T_A = 25°C, V_S = +5V, R_f = 200Ω, R_L = 500Ω to V_S/2; G = 10; unless otherwise noted.

Application Information

Basic Information

Figures 1 and 2 illustrate typical circuit configurations for non-inverting, inverting, and unity gain topologies for dual supply applications. They show the recommended bypass capacitor values and overall closed loop gain equations.

Figure 1: Typical Non-Inverting Gain Circuit

Figure 2: Typical Inverting Gain Circuit

Achieving Low Noise in an Application

Making full use of the low noise of the CLC1001 requires careful consideration of resistor values. The feedback and gain set resistors (R_f and R_g) and the non-inverting source impedance (R_{source}) all contribute noise to the circuit and can easily dominate the overall noise if their values are too high. The datasheet is specified with an R_g of 22.1Ω, at which point the noise from R_f and R_g is about equal to the noise from the CLC1001. Lower value resistors could be used at the expense of more distortion. Figure 3 shows total input voltage noise (amp+resistors) versus R_f and R_g. As the value of R_f increases, the total input referred noise also increases.

Figure 3: Input Referred Voltage Noise vs. R_f and R_g

The noise caused by a resistor is modeled with either a voltage source in series with the resistance:

$$\sqrt{4kTR}$$

Or a current source in parallel with it:

$$i_R = \sqrt{\frac{4kT}{R}}$$

Op amp noise is modeled with three noise sources, e_n, i_n, i_n and i_i. These three sources are analogous to the DC input voltage and current errors V_{os}, I_{bn} and I_{bi}.

The noise models must be analyzed in-circuit to determine the effect on the op amp output noise.

Since noise is statistical in nature rather than a continuous signal, the set of noise sources in circuit add in an RMS (root mean square) fashion rather than in a linear fashion. For uncorrelated noise sources, this means you add the squares of the noise voltages. A typical non-inverting application (see figure 1) results in the following noise at the output of the op amp:

$$e_o^2 = e_n^2 \left(1 + \frac{R_f}{R_g}\right)^2 + in^2 R_s^2 \left(1 + \frac{R_f}{R_g}\right)^2 + i_i^2 R_f^2$$

op amp noise terms e_n, i_n and i_i

$$+ e_{Rs}^2 \left(1 + \frac{R_f}{R_g}\right)^2 + e_{Rg}^2 \left(\frac{R_f}{R_g}\right)^2 + e_{Rf}^2$$

external resistor noise terms for R_S, R_g and R_f

High source impedances are sometimes unavoidable, but they increase noise from the source impedance and also make the circuit more sensitive to the op amp current noise. Analyze all noise sources in the circuit, not just the op amp itself, to achieve low noise in your application.

Power Dissipation

Power dissipation should not be a factor when operating under the stated 500Ω load condition. However, applications with low impedance, DC coupled loads should be analyzed to ensure that maximum allowed junction temperature is not exceeded. Guidelines listed below can be used to verify that the particular application will not cause the device to operate beyond it's intended operating range.

Maximum power levels are set by the absolute maximum junction rating of 150°C. To calculate the junction temperature, the package thermal resistance value Theta$_{JA}$ (θ_{JA}) is used along with the total die power dissipation.

$$T_{Junction} = T_{Ambient} + (\theta_{JA} \times P_D)$$

Where $T_{Ambient}$ is the temperature of the working environment.

In order to determine P_D, the power dissipated in the load needs to be subtracted from the total power delivered by the supplies.

$$P_D = P_{supply} - P_{load}$$

Supply power is calculated by the standard power equation.

$$P_{supply} = V_{supply} \times I_{RMSsupply}$$

$$V_{supply} = V_{S+} - V_{S-}$$

Power delivered to a purely resistive load is:

$$P_{load} = ((V_{load})_{RMS}^2)/Rload_{eff}$$

The effective load resistor (Rload$_{eff}$) will need to include the effect of the feedback network. For instance,

Rload$_{eff}$ in Figure 3 would be calculated as:

$$R_L \parallel (R_f + R_g)$$

These measurements are basic and are relatively easy to perform with standard lab equipment. For design purposes however, prior knowledge of actual signal levels and load impedance is needed to determine the dissipated power. Here, P_D can be found from

$$P_D = P_{Quiescent} + P_{Dynamic} - P_{load}$$

Quiescent power can be derived from the specified I_S values along with known supply voltage, V_{supply}. Load power can be calculated as above with the desired signal amplitudes using:

$$(V_{load})_{RMS} = V_{peak} / \sqrt{2}$$

$$(I_{load})_{RMS} = (V_{load})_{RMS} / Rload_{eff}$$

The dynamic power is focused primarily within the output stage driving the load. This value can be calculated as:

$$P_{Dynamic} = (V_{S+} - V_{load})_{RMS} \times (I_{load})_{RMS}$$

Assuming the load is referenced in the middle of the power rails or $V_{supply}/2$.

Figure 4 shows the maximum safe power dissipation in the package vs. the ambient temperature for the packages available.

Figure 4. Maximum Power Derating

Driving Capacitive Loads

Increased phase delay at the output due to capacitive loading can cause ringing, peaking in the frequency response, and possible unstable behavior. Use a series resistance, R_S, between the amplifier and the load to help improve stability and settling performance. Refer to Figure 5.

Figure 5. Addition of R_S for Driving Capacitive Loads

Table 1 provides the recommended R_S for various capacitive loads. The recommended R_S values result in approximately <1dB peaking in the frequency response. The Frequency Response vs. C_L plots, on page 6 and 7, illustrate the response of the CLC1001.

C_L (pF)	R_S (Ω)	-3dB BW (MHz)
10	43	266
22	33	228
47	20	192
100	13	155
470	4.3	84

Table 1: Recommended R_S vs. C_L

For a given load capacitance, adjust R_S to optimize the tradeoff between settling time and bandwidth. In general, reducing R_S will increase bandwidth at the expense of additional overshoot and ringing.

Overdrive Recovery

For an amplifier, an overdrive condition is defined as the point when either one of the inputs or the output exceed their specified voltage range. Overdrive recovery is the time needed for the amplifier to return to its normal or linear operating point. The recovery time varies based on whether the input or output is overdriven and by how much the ranges are exceeded. The CLC1001 will typically recover in less than 25ns from an overdrive condition. Figure 6 shows the CLC1001 in an overdriven condition.

Figure 6: Overdrive Recovery

Layout Considerations

General layout and supply bypassing play major roles in high frequency performance. Exar has evaluation boards to use as a guide for high frequency layout and as an aid in device testing and characterization. Follow the steps below as a basis for high frequency layout:

- Include 6.8µF and 0.1µF ceramic capacitors for power supply decoupling

- Place the 6.8µF capacitor within 0.75 inches of the power pin
- Place the 0.1µF capacitor within 0.1 inches of the power pin
- Remove the ground plane under and around the part, especially near the input and output pins to reduce parasitic capacitance
- Minimize all trace lengths to reduce series inductances

Refer to the evaluation board layouts below for more information.

Evaluation Board Information

The following evaluation boards are available to aid in the testing and layout of these devices:

Evaluation Board #	Products
CEB002	CLC1001 in TSOT
CEB003	CLC1001 in SOIC

Evaluation Board Schematics

Evaluation board schematics and layouts are shown in Figures 7-11 These evaluation boards are built for dual-supply operation. Follow these steps to use the board in a single-supply application:

1. Short -V_S to ground.
2. Use C3 and C4, if the -V_S pin of the amplifier is not directly connected to the ground plane.

Revision History

Revision	Date	Description
1H (ECN 1441-02)	September 2014	Reformat into Exar data sheet template. Updated ordering information table to include MTR and EVB part numbers. Increased "I" temperature range from +85 to +125°C. Removed "A" temp grade parts, since "I" is now equivalent. Updated thermal resistance numbers and package outline drawings.
