

## FEATURES

### Low power dissipation

#### AD7989-1

400  $\mu$ W at 100 kSPS (VDD only)

700  $\mu$ W at 100 kSPS (total)

#### AD7989-5

2 mW at 500 kSPS (VDD only)

3.5 mW at 500 kSPS (total)

### 18-bit resolution with no missing codes

Throughput: 100 kSPS (AD7989-1)/500 kSPS (AD7989-5)

INL:  $\pm 1$  LSB typical, 2 LSB maximum

SNR: 98 dB at 1 kHz,  $V_{REF} = 5$  V

SINAD: 97 dB at 1 kHz

THD:  $-120$  dB at 10 kHz

Dynamic range: 99 dB,  $V_{REF} = 5$  V

True differential analog input range:  $\pm V_{REF}$

0 V to  $V_{REF}$  with  $V_{REF}$  between 2.4 V and 5.1 V

No pipeline delay

Single-supply 2.5 V operation with 1.8 V/2.5 V/3 V/5 V logic interface

Proprietary serial interface: SPI-/QSPI™-/MICROWIRE™-/DSP-compatible<sup>1</sup>

Ability to daisy-chain multiple ADCs

10-lead package: MSOP and 3 mm  $\times$  3 mm LFCSP

## APPLICATIONS

Battery-powered equipment

Data acquisition systems

Medical instruments

Seismic data acquisition systems

## GENERAL DESCRIPTION

The AD7989-1/AD7989-5 are 18-bit, successive approximation, analog-to-digital converters (ADCs) that operate from a single power supply, VDD. They contain a low power, high speed, 18-bit sampling ADC and a versatile serial interface port. On the CNV rising edge, the AD7989-1/AD7989-5 sample the voltage difference between the IN+ and IN- pins. The voltages on these pins usually swing in opposite phases between 0 V and  $V_{REF}$ . The reference voltage, REF, is applied externally and can be set independent of the supply voltage, VDD. Its power scales linearly with throughput.

The AD7989-1/AD7989-5 are serial peripheral interface (SPI) compatible, which features the ability, using the SDI input, to daisy-chain several ADCs on a single 3-wire bus. It is compatible with 1.8 V, 2.5 V, 3 V, and 5 V logic, using the separate VIO supply.

The AD7989-1/AD7989-5 are available in a 10-lead MSOP or a 10-lead LFCSP with operation specified from  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ .

Table 1. MSOP, LFCSP 14-/16-/18-Bit PulsAR® ADCs

Signal-to-Noise Ratio	fIN = 1 kHz, VREF = 5 V, TA = 25°C	95.5	98		dB <sup>3</sup>
	fIN = 1 kHz, VREF = 2.5 V, TA = 25°C		92.5		dB <sup>3</sup>
Spurious-Free Dynamic Range	fIN = 10 kHz		–115		dB <sup>3</sup>
Total Harmonic Distortion <sup>5</sup>	fIN = 10 kHz		–120		dB <sup>3</sup>
Signal-to-Noise-and-Distortion Ratio	fIN = 1 kHz, VREF = 5 V, TA = 25°C		97		dB <sup>3</sup>

<sup>1</sup> LSB means least significant bit. With the ±5 V input range, 1 LSB is 38.15 µV.

<sup>2</sup> See the Terminology section. These specifications include full temperature range variation but not the error contribution from the external reference.

<sup>3</sup> All specifications expressed in decibels are referred to a full-scale input FSR and tested with an input signal at 0.5 dB below full scale, unless otherwise specified.

<sup>4</sup> Dynamic range is obtained by oversampling the ADC running at a throughput, fs, of 500 kSPS followed by postdigital filtering with an output word rate of fo.

<sup>5</sup> Tested fully in production at fIN = 1 kHz.

VDD = 2.5 V, VIO = 2.3 V to 5.5 V, REF = 5 V, TA = -40°C to +85°C, unless otherwise noted.

10-Lead LFCSP_WD	2.96°C/W
Reflow Soldering	JEDEC Standard (J-STD-020)

<sup>1</sup> See the Analog Inputs section for an explanation of IN+ and IN–.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

### ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

Figure 4. 10-Lead MSOP Pin Configuration

NOTES:  
1. THE EXPOSED PAD CAN BE CONNECTED TO GND.

Figure 5. 10-Lead LFCSP Pin Configuration

Table 6. Pin Function Descriptions

Pin No.	Mnemonic	Type <sup>1</sup>	Description
1	REF	AI	Reference Input Voltage. The REF range is 2.4 V to 5.1 V. This pin is referred to the GND pin and should be decoupled closely to the GND pin with a 10 μF capacitor.
2	VDD	P	Power Supply.
3	IN+	AI	Differential Positive Analog Input.
4	IN-	AI	Differential Negative Analog Input.
5	GND	P	Power Supply Ground.
6	CNV	DI	Conversion Input. This input has multiple functions. On its leading edge, it initiates the conversions and selects the interface mode of the device: chain mode or chip select (CS) mode. In CS mode, the SDO pin is enabled when CNV is low. In chain mode, the data is read when CNV is high.
7	SDO	DO	Serial Data Output. The conversion result is output on this pin. It is synchronized to SCK.
8	SCK	DI	Serial Data Clock Input. When the device is selected, the conversion result is shifted out by this clock.
9	SDI/CS	DI	Serial Data Input/Chip Select. This input has multiple functions. It selects the interface mode of the ADC as follows: Chain mode is selected if this pin is low during the CNV rising edge. In this mode, SDI/CS is used as a data input to daisy-chain the conversion results of two or more ADCs onto a single SDO line. The digital data level on SDI/CS is output on SDO with a delay of 16 SCK cycles. CS mode is selected if SDI/CS is high during the CNV rising edge. In this mode, either SDI/CS or CNV can enable the serial output signals when low.
10	VIO	P	Input/Output Interface Digital Power. This pin is nominally at the same supply as the host interface (1.8 V, 2.5 V, 3 V, or 5 V).
	EP		Exposed Pad. For the lead frame chip scale package (LFCSP), the exposed pad can be connected to GND. This connection is not required to meet the electrical performances.

<sup>1</sup>AI = analog input, DI = digital input, DO = digital output, and P = power.

## TERMINOLOGY

### Integral Nonlinearity Error (INL)

INL refers to the deviation of each individual code from a line drawn from negative full scale through positive full scale. The point used as negative full scale occurs  $\frac{1}{2}$  LSB before the first code transition. Positive full scale is defined as a level  $1\frac{1}{2}$  LSB beyond the last code transition. The deviation is measured from the middle of each code to the true straight line (see Figure 25).

### Differential Nonlinearity Error (DNL)

In an ideal ADC, code transitions are 1 LSB apart. DNL is the maximum deviation from this ideal value. It is often specified in terms of resolution for which no missing codes are guaranteed.

### Zero Error

Zero error is the difference between the ideal midscale voltage, that is, 0 V, and the actual voltage producing the midscale output code, that is, 0 LSB.

### Gain Error

The first transition (from 100 ... 00 to 100 ... 01) should occur at a level  $\frac{1}{2}$  LSB above nominal negative full scale ( $-4.999981$  V for the  $\pm 5$  V range). The last transition (from 011 ... 10 to 011 ... 11) occurs for an analog voltage  $1\frac{1}{2}$  LSB below the nominal full scale ( $+4.999943$  V for the  $\pm 5$  V range). The gain error is the deviation of the difference between the actual level of the last transition and the actual level of the first transition from the difference between the ideal levels.

### Spurious-Free Dynamic Range (SFDR)

SFDR is the difference, in decibels (dB), between the rms amplitude of the input signal and the peak spurious signal.

### Effective Number of Bits (ENOB)

ENOB is a measurement of the resolution with a sine wave input. It is related to SINAD as follows:

$$ENOB = (SINAD_{dB} - 1.76)/6.02$$

and is expressed in bits.

### Noise-Free Code Resolution

Noise-free code resolution is the number of bits beyond which it is impossible to distinctly resolve individual codes. It is calculated as

$$Noise\text{-Free Code Resolution} = \log_2(2^N/Peak\text{-to-Peak Noise})$$

and is expressed in bits.

### Effective Resolution

Effective resolution is calculated as

$$Effective\ Resolution = \log_2(2^N/RMS\ Input\ Noise)$$

and is expressed in bits.

### Total Harmonic Distortion (THD)

THD is the ratio of the rms sum of the first five harmonic components to the rms value of a full-scale input signal and is expressed in decibels.

### Dynamic Range

Dynamic range is the ratio of the rms value of the full scale to the total rms noise measured with the inputs shorted together. The value for dynamic range is expressed in decibels. It is measured with a signal at  $-60$  dB so that it includes all noise sources and DNL artifacts.

### Signal-to-Noise Ratio (SNR)

SNR is the ratio of the rms value of the actual input signal to the rms sum of all other spectral components below the Nyquist frequency, excluding harmonics and dc. The value for SNR is expressed in decibels.

### Signal-to-Noise-and-Distortion (SINAD) Ratio

SINAD is the ratio of the rms value of the actual input signal to the rms sum of all other spectral components that are less than the Nyquist frequency, including harmonics but excluding dc. The value of SINAD is expressed in decibels.

### Aperture Delay

Aperture delay is the measure of the acquisition performance and is the time between the rising edge of the CNV input and when the input signal is held for a conversion.

### Transient Response

Transient response is the time required for the ADC to accurately acquire its input after a full-scale step function is applied.

## THEORY OF OPERATION

Figure 24. ADC Simplified Schematic

### CIRCUIT INFORMATION

The **AD7989-1/AD7989-5** are high speed, low power, single-supply, precise, 18-bit ADCs using a successive approximation architecture.

The **AD7989-5** is capable of converting 500,000 samples per second (500 kSPS), whereas the **AD7989-1** is capable of converting 100,000 samples per second (100 kSPS), and they power down between conversions. When operating at 100 kSPS, the ADC typically consumes 700  $\mu$ W, making the **AD7989-1** ideal for battery-powered applications.

The **AD7989-1/AD7989-5** provide the user with an on-chip track-and-hold amplifier and do not exhibit any pipeline delay or latency, making these devices ideal for multiple multiplexed channel applications.

The **AD7989-1/AD7989-5** can be interfaced to any 1.8 V to 5 V digital logic family. It is available in a 10-lead MSOP or a tiny 10-lead LFCSP that allows space savings and flexible configurations.

### CONVERTER OPERATION

The **AD7989-1/AD7989-5** are a successive approximation ADCs based on a charge redistribution digital-to-analog converter (DAC). Figure 24 shows the simplified schematic of the ADC. The capacitive DAC consists of two identical arrays of 18 binary-weighted capacitors, which are connected to the two comparator inputs.

During the acquisition phase, terminals of the array tied to the input of the comparator are connected to GND via SW+ and SW-. All independent switches are connected to the analog inputs. Therefore, the capacitor arrays are used as sampling capacitors and acquire the analog signal on the IN+ and IN- inputs. When the acquisition phase is complete and the CNV input goes high, a conversion phase is initiated. When the conversion phase begins, SW+ and SW- are opened first. The two capacitor arrays are then disconnected from the inputs and connected to the GND input. Therefore, the differential voltage between the IN+ and IN- inputs captured at the end of the acquisition phase is applied to the comparator inputs, causing the comparator to become unbalanced. By switching each element of the capacitor array between GND and REF, the comparator input varies by binary-weighted voltage steps ( $V_{REF}/2, V_{REF}/4 \dots V_{REF}/262,144$ ). The control logic toggles these switches, starting with the MSB, to bring the comparator back into a balanced condition. After the completion of this process, the device returns to the acquisition phase, and the control logic generates the ADC output code.

Because the **AD7989-1/AD7989-5** have an on-board conversion clock, the serial clock, SCK, is not required for the conversion process.

**Transfer Functions**

The ideal transfer characteristic for the AD7989-1/AD7989-5 is shown in Figure 25 and Table 7.

Figure 25. ADC Ideal Transfer Function

Table 7. Output Codes and Ideal Input Voltages

Description	Analog Input $V_{REF} = 5\text{ V}$	Digital Output Code (Hex)
+FSR - 1 LSB	+4.999962 V	0x1FFFF <sup>1</sup>
Midscale + 1 LSB	+38.15 $\mu\text{V}$	0x00001
Midscale	0 V	0x00000
Midscale - 1 LSB	-38.15 $\mu\text{V}$	0x3FFFF
-FSR + 1 LSB	-4.999962 V	0x20001
-FSR	-5 V	0x20000 <sup>2</sup>

<sup>1</sup> This is also the code for an overranged analog input ( $V_{IN+} - V_{IN-}$  above  $V_{REF} - V_{GND}$ ).  
<sup>2</sup> This is also the code for an underranged analog input ( $V_{IN+} - V_{IN-}$  below  $V_{GND}$ ).

**TYPICAL CONNECTION DIAGRAM**

Figure 26 shows an example of the recommended connection diagram for the AD7989-1/AD7989-5 when multiple supplies are available.

<sup>1</sup>SEE THE VOLTAGE REFERENCE INPUT SECTION FOR REFERENCE SELECTION.  
<sup>2</sup> $C_{REF}$  IS USUALLY A 10 $\mu\text{F}$  CERAMIC CAPACITOR (X5R).  
<sup>3</sup>SEE THE RECOMMENDED LAYOUT IN FIGURE 39 AND FIGURE 40.  
<sup>4</sup>SEE THE DRIVER AMPLIFIER CHOICE SECTION.  
<sup>5</sup>OPTIONAL FILTER. SEE THE ANALOG INPUTS SECTION.

Figure 26. Typical Application Diagram with Multiple Supplies

**ANALOG INPUTS**

Figure 27 shows an equivalent circuit of the input structure of the AD7989-1/AD7989-5.

The two diodes, D1 and D2, provide ESD protection for the analog inputs, IN+ and IN-. Care must be taken to ensure that the analog input signal does not exceed the reference input voltage (REF) by more than 0.3 V. If the analog input signal exceeds this level, the diodes become forward-biased and start conducting current. These diodes can handle a forward-biased current of 130 mA maximum. However, if the supplies of the input buffer (for example, the supplies of the ADA4841-x in Figure 26) are different from those of REF, the analog input signal may eventually exceed the supply rails by more than 0.3 V. In such a case (for example, an input buffer with a short circuit), the current limitation can be used to protect the device.

Figure 27. Equivalent Analog Input Circuit

The analog input structure allows the sampling of the true differential signal between IN+ and IN-. By using these differential inputs, signals common to both inputs are rejected.

Figure 28. Analog Input CMRR vs. Frequency

During the acquisition phase, the impedance of the analog inputs (IN+ or IN-) can be modeled as a parallel combination of Capacitor C<sub>PIN</sub> and the network formed by the series connection of R<sub>IN</sub> and C<sub>IN</sub>. C<sub>PIN</sub> is primarily the pin capacitance. R<sub>IN</sub> is typically 400 Ω and is a lumped component composed of serial resistors and the on resistance of the switches. C<sub>IN</sub> is typically 30 pF and is mainly the ADC sampling capacitor.

During the sampling phase, when the switches are closed, the input impedance is limited to C<sub>PIN</sub>. R<sub>IN</sub> and C<sub>IN</sub> make a one-pole, low-pass filter that reduces undesirable aliasing effects and limits noise.

When the source impedance of the driving circuit is low, the AD7989-1/AD7989-5 can be driven directly. Large source impedances significantly affect the ac performance, especially THD. The dc performances are less sensitive to the input impedance. The maximum source impedance depends on the amount of THD that can be tolerated. The THD degrades as a function of the source impedance and the maximum input frequency.

**DRIVER AMPLIFIER CHOICE**

Although the AD7989-1/AD7989-5 is easy to drive, the driver amplifier must meet the following requirements:

- The noise generated by the driver amplifier must be kept as low as possible to preserve the SNR and transition noise performance of the AD7989-1/AD7989-5. The noise from the driver is filtered by the one-pole, low-pass filter of the AD7989-1/AD7989-5 analog input circuit made by R<sub>IN</sub> and C<sub>IN</sub> or by the external filter, if one is used. Because the typical noise of the AD7989-1/AD7989-5 is 40 μV rms, the SNR degradation due to the amplifier is

$$SNR_{LOSS} = 20 \log \left( \frac{40}{\sqrt{40^2 + \frac{\pi}{2} f_{-3dB} (Ne_N)^2}} \right)$$

- where:
  - f<sub>-3dB</sub> is the input bandwidth, in megahertz, of the AD7989-1/AD7989-5 (10 MHz) or the cutoff frequency of the input filter, if one is used.
  - N is the noise gain of the amplifier (for example, 1 in buffer configuration).
  - e<sub>N</sub> is the equivalent input noise voltage of the op amp, in nV/√Hz.
- For ac applications, use a driver with a THD performance commensurate with the AD7989-1/AD7989-5.
- For multichannel multiplexed applications, the driver amplifier and the AD7989-1/AD7989-5 analog input circuit must settle for a full-scale step onto the capacitor array at an 18-bit level (0.0004%, 4 ppm). In the data sheet of the amplifier, settling at 0.1% to 0.01% is more commonly specified. This settling may differ significantly from the settling time at an 18-bit level and must be verified prior to driver selection.

Table 8. Recommended Driver Amplifiers<sup>1</sup>

Amplifier	Typical Application
ADA4941-1	Very low noise, low power, single to differential
ADA4841-1/ ADA4841-2	Very low noise, small, and low power
AD8021	Very low noise and high frequency
AD8022	Low noise and high frequency
OP184	Low power, low noise, and low frequency
AD8655	5 V single supply, low noise
AD8605, AD8615	5 V single supply, low power

<sup>1</sup> For the latest recommended drivers, see the product recommendations listed on the product webpage.

**SINGLE-TO-DIFFERENTIAL DRIVER**

For applications using a single-ended analog signal, either bipolar or unipolar, the [ADA4941-1](#) single-ended-to-differential driver allows a differential input to the device. The schematic is shown in Figure 29.

R1 and R2 set the attenuation ratio between the input range and the ADC range ( $V_{REF}$ ). R1, R2, and  $C_F$  are chosen depending on the desired input resistance, signal bandwidth, antialiasing, and noise contribution. For example, for the  $\pm 10$  V range with a 4 k $\Omega$  impedance, R2 = 1 k $\Omega$  and R1 = 4 k $\Omega$ .

R3 and R4 set the common mode on the IN $^-$  input, and R5 and R6 set the common mode on the IN $^+$  input of the ADC. Make sure that the common mode is close to  $V_{REF}/2$ . For example, for the  $\pm 10$  V range with a single supply, R3 = 8.45 k $\Omega$ , R4 = 11.8 k $\Omega$ , R5 = 10.5 k $\Omega$ , and R6 = 9.76 k $\Omega$ .

Figure 29. Single-Ended-to-Differential Driver Circuit

**VOLTAGE REFERENCE INPUT**

The [AD7989-1/AD7989-5](#) voltage reference input, REF, has a dynamic input impedance and must, therefore, be driven by a low impedance source with efficient decoupling between the REF and GND pins, as explained in the Layout section.

When REF is driven by a very low impedance source (for example, a reference buffer using the [AD8031](#) or the [AD8605](#)), a 10  $\mu$ F (X5R, 0805 size) ceramic chip capacitor is appropriate for optimum performance.

If an unbuffered reference voltage is used, the decoupling value depends on the reference used. For instance, a 22  $\mu$ F (X5R, 1206 size) ceramic chip capacitor is appropriate for optimum performance using a low temperature drift [ADR43x](#) reference.

If desired, a reference decoupling capacitor with values as small as 2.2  $\mu$ F can be used with a minimal impact on performance, especially DNL.

Regardless, there is no need for an additional lower value ceramic decoupling capacitor (for example, 100 nF) between the REF and GND pins.

**POWER SUPPLY**

The [AD7989-1/AD7989-5](#) use two power supply pins: a core supply (VDD) and a digital input/output interface supply (VIO). VIO allows direct interface with any logic between 1.8 V and 5.5 V. To reduce the number of supplies needed, VIO and VDD can be tied together. The [AD7989-1/AD7989-5](#) are independent of power supply sequencing between VIO and VDD. Additionally, they are insensitive to power supply variations over a wide frequency range, as shown in Figure 30.

Figure 30. PSRR vs. Frequency

The [AD7989-1/AD7989-5](#) power down automatically at the end of each conversion phase.

**DIGITAL INTERFACE**

Although the [AD7989-1/AD7989-5](#) have a reduced number of pins, they offer flexibility in their serial interface modes.

When in  $\overline{CS}$  mode, the [AD7989-1/AD7989-5](#) are compatible with SPI, QSPI, digital hosts, and DSPs. In this mode, the [AD7989-1/AD7989-5](#) can use either a 3-wire or 4-wire interface. A 3-wire interface using the CNV, SCK, and SDO signals minimizes wiring connections, which is useful, for instance, in isolated applications. A 4-wire interface using the SDI/ $\overline{CS}$ , CNV, SCK, and SDO signals allows CNV, which initiates the conversions, to be independent of the readback timing (SDI). This is useful in low jitter sampling or simultaneous sampling applications.

When in chain mode, the [AD7989-1/AD7989-5](#) provide a daisy-chain feature using the SDI input for cascading multiple ADCs on a single data line, similar to a shift register.

The mode in which the device operates depends on the SDI/ $\overline{CS}$  level when the CNV rising edge occurs.  $\overline{CS}$  mode is selected if SDI/ $\overline{CS}$  is high, and chain mode is selected if SDI/ $\overline{CS}$  is low. The SDI/ $\overline{CS}$  hold time is such that when SDI/ $\overline{CS}$  and CNV are connected together, chain mode is always selected. The user must time out the maximum conversion time prior to readback.

**$\overline{CS}$  MODE, 3-WIRE**

This mode is usually used when a single AD7989-1/AD7989-5 is connected to an SPI-compatible digital host. The connection diagram is shown in Figure 31, and the corresponding timing is given in Figure 32.

With  $\overline{SDI}/\overline{CS}$  tied to  $\overline{VIO}$ , a rising edge on  $\overline{CNV}$  initiates a conversion, selects the  $\overline{CS}$  mode, and forces  $\overline{SDO}$  to high impedance. When the conversion is complete, the AD7989-1/

AD7989-5 enter the acquisition phase and power down. When  $\overline{CNV}$  goes low, the MSB is output onto  $\overline{SDO}$ . The remaining data bits are clocked by subsequent  $\overline{SCK}$  falling edges. The data is valid on both  $\overline{SCK}$  edges. Although the rising edge can be used to capture the data, a digital host using the  $\overline{SCK}$  falling edge allows a faster reading rate, provided that it has an acceptable hold time. After the 18<sup>th</sup>  $\overline{SCK}$  falling edge or when  $\overline{CNV}$  goes high (whichever occurs first),  $\overline{SDO}$  returns to high impedance.

Figure 31.  $\overline{CS}$  Mode, 3-Wire Connection Diagram (SDI High)

Figure 32.  $\overline{CS}$  Mode, 3-Wire Serial Interface Timing (SDI High)

**CS MODE, 4-WIRE**

This mode is usually used when multiple AD7989-1/AD7989-5 devices are connected to an SPI-compatible digital host.

A connection diagram example using two AD7989-1/AD7989-5 devices is shown in Figure 33, and the corresponding timing is given in Figure 34.

With SDI high, a rising edge on CNV initiates a conversion, selects SDI/CS mode, and forces SDO to high impedance. In this mode, CNV must be held high during the conversion phase and the subsequent data readback. (If SDI/CS and CNV are low, SDO is driven low.) Prior to the minimum conversion time, SDI/CS can be used to select other SPI devices, such as analog multiplexers, but SDI/CS must be returned high before the

minimum conversion time elapses and then held high for the maximum possible conversion time. When the conversion is complete, the AD7989-1/AD7989-5 enter the acquisition phase and power down. Each ADC result can be read by bringing its SDI/CS input low, which consequently outputs the MSB onto SDO. The remaining data bits are then clocked by subsequent SCK falling edges. The data is valid on both SCK edges. Although the rising edge can be used to capture the data, a digital host using the SCK falling edge allows a faster reading rate, provided that it has an acceptable hold time. After the 18<sup>th</sup> SCK falling edge or when SDI/CS goes high (whichever occurs first), SDO returns to high impedance and another AD7989-1/AD7989-5 can be read.

Figure 33. CS Mode, 4-Wire Connection Diagram

Figure 34. CS Mode, 4-Wire Serial Interface Timing

**CHAIN MODE**

This mode can be used to daisy-chain multiple AD7989-1/AD7989-5 devices on a 3-wire serial interface. This feature is useful for reducing component count and wiring connections, for example, in isolated multiconverter applications or for systems with a limited interfacing capacity. Data readback is analogous to clocking a shift register.

A connection diagram example using two AD7989-1/AD7989-5 devices is shown in Figure 35, and the corresponding timing is given in Figure 36.

When SDI/ $\overline{\text{CS}}$  and CNV are low, SDO is driven low. With SCK low, a rising edge on CNV initiates a conversion, and selects the chain mode. In this mode, CNV is held high during the

conversion phase and the subsequent data readback. When the conversion is complete, the MSB is output onto SDO and the AD7989-1/AD7989-5 enter the acquisition phase and power down. The remaining data bits stored in the internal shift register are clocked by subsequent SCK falling edges. For each ADC, SDI feeds the input of the internal shift register and is clocked by the SCK falling edge. Each ADC in the chain outputs its data MSB first, and  $18 \times N$  clocks are required to read back the N ADCs. The data is valid on both SCK edges. Although the rising edge can be used to capture the data, a digital host using the SCK falling edge allows a faster reading rate and, consequently, more AD7989-1/AD7989-5 devices in the chain, provided that the digital host has an acceptable hold time. The maximum conversion rate may be reduced due to the total readback time.

## APPLICATIONS INFORMATION

### INTERFACING TO BLACKFIN® DSP

The AD7989-1/AD7989-5 can easily connect to a DSP SPI or SPORT. The SPI configuration is straightforward using the standard SPI interface, as shown in Figure 37.

Figure 37. Typical Connection to Blackfin SPI Interface

Similarly, the SPORT interface can be used to interface to this ADC. The SPORT interface has some benefits in that it can use direct memory access (DMA) and provides a lower jitter CNV signal generated from a hardware counter.

Some glue logic may be required between SPORT and the AD7989-1/AD7989-5 interface. The evaluation board for the AD7989-1/AD7989-5 interfaces directly to the SPORT of the Blackfin-based (ADSP-BF527) SDP board. The configuration used for the SPORT interface requires the addition of some glue logic as shown in Figure 38. The SCK input to the ADC was gated off when CNV was high to keep the SCK line static while converting the data, thereby ensuring the best integrity of the result. This approach uses an AND gate and a NOT gate for the SCK path. The other logic gates used on the RSCLK and RFS paths are for delay matching purposes and may not be necessary when path lengths are short.

This is one approach to using the SPORT interface for this ADC; there may be other solutions similar to this approach.

Figure 38. Evaluation Board Connection to Blackfin Sport Interface

### LAYOUT

Design the printed circuit board that houses the AD7989-1/AD7989-5 so that the analog and digital sections are separated and confined to certain areas of the board. The pinout of the AD7989-1/AD7989-5, with its analog signals on the left side and its digital signals on the right side, eases this task.

Avoid running digital lines under the device because these couple noise onto the die, unless a ground plane under the AD7989-1/AD7989-5 is used as a shield. Do not run fast switching signals, such as CNV or clocks, near analog signal paths. Avoid crossover of digital and analog signals.

Using at least one ground plane is recommended. It can be common or split between the digital and analog sections. In the latter case, join the planes underneath the AD7989-1/AD7989-5 devices.

The AD7989-1/AD7989-5 voltage reference input, REF, has a dynamic input impedance. Decouple REF with minimal parasitic inductances by placing the reference decoupling ceramic capacitor close to, but ideally right up against, the REF and GND pins and connecting them with wide, low impedance traces.

Finally, decouple the power supplies of the AD7989-1/AD7989-5, VDD and VIO, with ceramic capacitors, typically 100 nF, placed close to the AD7989-1/AD7989-5 and connected using short, wide traces to provide low impedance paths and to reduce the effect of glitches on the power supply lines.

An example of a layout following these rules is shown in Figure 39 and Figure 40.

**EVALUATING AD7989-1/AD7989-5 PERFORMANCE**

Other recommended layouts for the AD7989-1/AD7989-5 are outlined in UG-340, the user guide of the evaluation board for the AD7989-1/AD7989-5 (EVAL-AD7989-5SDZ). The evaluation board package includes a fully assembled and tested evaluation board, the user guide, and software for controlling the board from a PC via the EVAL-SDP-CB1Z.
