2. R_{θJA} is the sum of the junction-to-case and case-to-ambient thermal resistance where the case thermal reference is defined as the solder mounting surface of the drain pins. R_{θJC} is guaranteed by design while R_{θCA} is determined by the user's board design.

$$P_D(t) = \frac{T_J - T_A}{R_{\theta J A}(t)} = \frac{T_J - T_A}{R_{\theta J C} + R_{\theta CA}(t)} = I_D^2(t) \times R_{DS(ON)}@T_J$$

FDC6323L Load Switch Application

APPLICATION CIRCUIT

General Description

This device is particularly suited for compact computer peripheral switching applications where 8V input and 1A output current capability are needed. This load switch integrates a small N-Channel Power MOSFET (Q1) which drives a large P-Channel Power MOSFET (Q2) in one tiny SuperSOT™-6 package.

A load switch is usually configured for high side switching so that the load can be isolated from the active power source. A P-Channel Power MOSFET, because it does not require its drive voltage above the input voltage, is usually more cost effective than using an N-Channel device in this particular application. A large P-Channel Power MOSFET minimizes voltage drop. By using a small N-Channel device the driving stage is simplified.

Component Values

R1	Typical 10k - 1MΩ
R2	Typical 0 - 100kΩ (optional)
C1	Typical 1000pF (optional)

Design Notes

- R1 is needed to turn off Q2.
- R2 can be used to soft start the switch in case the output capacitance Co is small.
- R2 should be at least 10 times smaller than R1 to guarantee Q1 turns on.
- By using R1 and R2 a certain amount of current is lost from the input. This bias current loss is given by the equation
$$I_{BIAS_LOSS} = \frac{V_{in}}{R1 + R2}$$
when the switch is ON. I_{BIAS_LOSS} can be minimized by selecting a large value for R1.
- R2 and C_{RSS} of Q2 make ramp for slow turn on. If excessive overshoot current occurs due to fast turn on, additional capacitance C1 can be added externally to slow down the turn on.
