

# System Ready, 18-Bit ±1 LSB INL, Voltage Output DAC

Data Sheet AD5780

#### **FEATURES**

True 18-bit voltage output DAC, ±1 LSB INL 8 nV/√Hz output noise spectral density 0.025 LSB long-term linearity error stability ±0.018 ppm/°C gain error temperature coefficient 2.5 µs output voltage settling time 3.5 nV-sec midscale glitch impulse Integrated precision reference buffers Operating temperature range: −40°C to +125°C 4 mm × 5 mm LFCSP package Wide power supply range of up to ±16.5 V 35 MHz Schmitt triggered digital interface 1.8 V-compatible digital interface

#### **APPLICATIONS**

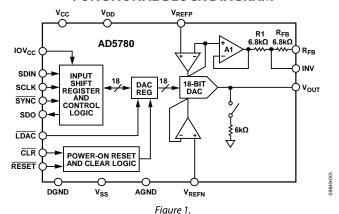

Medical instrumentation
Test and measurement
Industrial control
Scientific and aerospace instrumentation
Data acquisition systems
Digital gain and offset adjustment
Power supply control

#### **GENERAL DESCRIPTION**

The AD5780¹ is a true 18-bit, unbuffered voltage output DAC that operates from a bipolar supply of up to 33 V. The AD5780 accepts a positive reference input range of 5 V to  $V_{DD}$  – 2.5 V and a negative reference input range of  $V_{SS}$  + 2.5 V to 0 V. Both reference inputs are buffered on chip and external buffers are not required. The AD5780 offers a relative accuracy specification of  $\pm 1$  LSB maximum range, and operation is guaranteed monotonic with a  $\pm 1$  LSB DNL maximum range specification.

The part uses a versatile 3-wire serial interface that operates at clock rates of up to 35 MHz and is compatible with standard SPI, QSPI™, MICROWIRE™, and DSP interface standards. The part incorporates a power-on reset circuit that ensures that the DAC output powers up to 0 V in a known output impedance state and remains in this state until a valid write to the device takes place. The part provides an output clamp feature that places the output in a defined load state.

#### FUNCTIONAL BLOCK DIAGRAM

**Table 1. Related Devices** 

| Part No.        | Description                    |
|-----------------|--------------------------------|
| Part No.        | Description                    |
| AD5790          | 20-bit, 2 LSB accurate DAC     |
| AD5791          | 20-bit, 1 ppm accurate DAC     |
| AD5781          | 18-bit, 0.5 LSB accurate DAC   |
| AD5541A/AD5542A | 16-bit, 1 LSB accurate 5 V DAC |
| AD5760          | 16-bit, 0.5 LSB accurate DAC   |

#### **PRODUCT HIGHLIGHTS**

- 1. True 18-bit accuracy.
- 2. Wide power supply range of up to  $\pm 16.5$  V.
- 3. -40°C to +125°C operating temperature range.
- Low 8 nV/√Hz noise.
- 5. Low ±0.018 ppm/°C gain error temperature coefficient.

<sup>&</sup>lt;sup>1</sup> Temperature range:  $-40^{\circ}$ C to  $+125^{\circ}$ C, typical conditions:  $T_A = 25^{\circ}$ C,  $V_{DD} = +15$  V,  $V_{SS} = -15$  V,  $V_{REFP} = +10$  V,  $V_{REFN} = -10$  V.

<sup>2</sup> Performance characterized with the AD8675ARZ output buffer.

<sup>3</sup> Linearity error refers to both INL error and DNL error, either parameter can be expected to drift by the amount specified after the length of time specified.

<sup>4</sup> The AD5780 is configured in the unity-gain mode with a low-pass RC filter on the output.  $R = 300 \Omega$ , C = 143 pF (total capacitance seen by the output buffer, lead capacitance, and so forth).

<sup>5</sup> Current flowing in an individual logic pin.

#### **TIMING CHARACTERISTICS**

 $V_{\text{CC}}$  = 2.7 V to 5.5 V; all specifications  $T_{\text{MIN}}$  to  $T_{\text{MAX}}$ , unless otherwise noted.

| Soldering   | J-STD-020   |  |  |
| ESD (Human Body Model)                              | 1.6 kV  |  |  |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

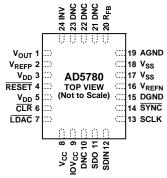

This device is a high performance integrated circuit with an ESD rating of 1.6 kV, and it is ESD sensitive. Proper precautions must be taken for handling and assembly.

#### **ESD CAUTION**

**ESD** (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

# PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES
1. DNC = DO NOT CONNECT. DO NOT CONNECT TO THIS PIN.
2. NEGATIVE ANALOG SUPPLY CONNECTION (VSS).
A VOLTAGE IN THE RANGE OF -16.5 V TO -2.5 V
CAN BE CONNECTED. VSS HOULD BE DECOUPLED
TO AGND. THE PADDLE CAN BE LEFT ELECTRICALLY
UNCONNECTED PROVIDED THAT A SUPPLY
CONNECTION IS MADE AT THE VSS PINS. IT IS
RECOMMENDED THAT THE PADDLE BE THERMALLY
CONNECTED TO A COPPER PLANE FOR ENHANCED
THERMAL PERFORMANCE.

Figure 4. Pin Configuration

Figure 4. Pin Configuration

**Table 5. Pin Function Descriptions** 

| Pin No.           | Mnemonic          | Description  |
|-------------------|-------------------|--|
| 1                 | V <sub>OUT</sub>  | Analog Output Voltage.   |
| 2                 | $V_{REFP}$        | Positive Reference Voltage Input. A voltage in the range of 5 V to V <sub>DD</sub> – 2.5 V can be connected to this pin.   |
| 3, 5              | V <sub>DD</sub>   | Positive Analog Supply Connection. A voltage in the range of 7.5 V to 16.5 V can be connected to this pin. V <sub>DD</sub> must be decoupled to AGND.  |
| 4                 | RESET             | Active Low Reset. Asserting this pin returns the AD5780 to its power-on status.  |
| 6                 | CLR               | Active Low Input. Asserting this pin sets the DAC register to a user defined value (see Table 12) and updates the DAC output. The output value depends on the DAC register coding that is being used, either binary or twos complement.  |
| 7                 | LDAC              | Active Low Load DAC Logic Input. This pin is used to update the DAC register and, consequently, the analog output. When tied permanently low, the output is updated on the rising edge of SYNC. If LDAC is held high during the write cycle, the input register is updated, but the output update is held off until the falling edge of LDAC. Do not leave the LDAC pin unconnected.           |
| 8                 | V <sub>CC</sub>   | Digital Supply. Voltage range is from 2.7 V to 5.5 V. V <sub>CC</sub> should be decoupled to DGND.   |
| 9                 | IOV <sub>CC</sub> | Digital Interface Supply. Digital threshold levels are referenced to the voltage applied to this pin. Voltage range is from 1.71 V to 5.5 V.   |
| 10, 21,<br>22, 23 | DNC               | Do Not Connect. Do not connect to these pins.  |
| 11                | SDO               | Serial Data Output. Data is clocked out on the rising edge of the serial clock input.  |
| 12                | SDIN              | Serial Data Input. This device has a 24-bit input shift register. Data is clocked into the register on the falling edge of the serial clock input.   |
| 13                | SCLK              | Serial Clock Input. Data is clocked into the input shift register on the falling edge of the serial clock input. Data can be transferred at rates of up to 35 MHz.   |
| 14                | SYNC              | Level Triggered Control Input (Active Low). This is the frame synchronization signal for the input data. When SYNC goes low, it enables the input shift register, and data is then transferred in on the falling edges of the following clocks. The DAC is updated on the rising edge of SYNC.   |
| 15                | DGND              | Ground Reference Pin for Digital Circuitry.  |
| 16                | $V_{REFN}$        | Negative Reference Voltage Input.  |
| 17, 18            | V <sub>SS</sub>   | Negative Analog Supply Connection. A voltage in the range of $-16.5$ V to $-2.5$ V can be connected to this pin. Vss must be decoupled to AGND.  |
| 19                | AGND              | Ground Reference Pin for Analog Circuitry.   |
| 20                | R <sub>FB</sub>   | Feedback Connection for External Amplifier. See the AD5780 Features section for further details.   |
| 24                | INV               | Inverting Input Connection for External Amplifier. See the AD5780 Features section for further details.  |
| EPAD              | Vss               | Negative Analog Supply Connection ( $V_{SS}$ ). A voltage in the range of $-16.5$ V to $-2.5$ V can be connected to this pin. $V_{SS}$ must be decoupled to AGND. The paddle can be left electrically unconnected provided that a supply connection is made at the $V_{SS}$ pins. It is recommended that the paddle be thermally connected to a copper plane for enhanced thermal performance. |

## **TERMINOLOGY**

#### **Relative Accuracy**

Relative accuracy, or integral nonlinearity (INL), is a measure of the maximum deviation, in LSB, from a straight line passing through the endpoints of the DAC transfer function. A typical INL error vs. code plot is shown in Figure 5.

#### Differential Nonlinearity (DNL)

Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of  $\pm 1$  LSB maximum ensures monotonicity. This DAC is guaranteed monotonic. A typical DNL error vs. code plot is shown in Figure 9.

#### **Linearity Error Long-Term Stability**

Linearity error long-term stability is a measure of the stability of the linearity of the DAC over a long period of time. It is specified in LSB for a time period of 500 hours and 1000 hours at an elevated ambient temperature.

#### **Zero-Scale Error**

Zero-scale error is a measure of the output error when zero-scale code (0x00000) is loaded to the DAC register. Ideally, the output voltage should be  $V_{\text{REFN}}$ . Zero-scale error is expressed in LSBs.

#### **Zero-Scale Error Temperature Coefficient**

Zero-scale error temperature coefficient is a measure of the change in zero-scale error with a change in temperature. It is expressed in ppm FSR/°C.

#### **Full-Scale Error**

Full-scale error is a measure of the output error when full-scale code (0x3FFFF) is loaded to the DAC register. Ideally, the output voltage should be  $V_{\text{REFP}}-1$  LSB. Full-scale error is expressed in LSBs.

#### **Full-Scale Error Temperature Coefficient**

Full-scale error temperature coefficient is a measure of the change in full-scale error with a change in temperature. It is expressed in ppm FSR/°C.

#### **Gain Error**

Gain error is a measure of the span error of the DAC. It is the deviation in slope of the DAC transfer characteristic from the ideal, expressed in ppm of the full-scale range.

#### **Gain Error Temperature Coefficient**

Gain error temperature coefficient is a measure of the change in gain error with a change in temperature. It is expressed in ppm FSR/°C.

#### **Midscale Error**

Midscale error is a measure of the output error when midscale code (0x20000) is loaded to the DAC register. Ideally, the output voltage should be  $(V_{REFP} - V_{REFN})/2 + V_{REFN}$ . Midscale error is expressed in LSBs.

#### **Output Voltage Settling Time**

Output voltage settling time is the amount of time it takes for the output voltage to settle to a specified level for a specified change in voltage. For fast settling applications, a high speed buffer amplifier is required to buffer the load from the 3.4 k $\Omega$  output impedance of the AD5780, in which case, it is the amplifier that determines the settling time.

#### Digital-to-Analog Glitch Impulse

Digital-to-analog glitch impulse is the impulse injected into the analog output when the input code in the DAC register changes state. It is specified as the area of the glitch in nV-sec and is measured when the digital input code is changed by 1 LSB at the major carry transition (see Figure 48).

#### **Output Enabled Glitch Impulse**

Output enabled glitch impulse is the impulse injected into the analog output when the clamp to ground on the DAC output is removed. It is specified as the area of the glitch in nV-sec (see Figure 48).

#### Digital Feedthrough

Digital feedthrough is a measure of the impulse injected into the analog output of the DAC from the digital inputs of the DAC but is measured when the DAC output is not updated. It is specified in nV-sec and measured with a full-scale code change on the data bus, that is, from all 0s to all 1s, and vice versa.

#### **Total Harmonic Distortion (THD)**

Total harmonic distortion is the ratio of the rms sum of the harmonics of the DAC output to the fundamental value. Only the second to fifth harmonics are included.

#### DC Power Supply Rejection Ratio

DC power supply rejection ratio is a measure of the rejection of the output voltage to dc changes in the power supplies applied to the DAC. It is measured for a given dc change in power supply voltage and is expressed in  $\mu V/V$ .

#### AC Power Supply Rejection Ratio (AC PSRR)

AC power supply rejection ratio is a measure of the rejection of the output voltage to ac changes in the power supplies applied to the DAC. It is measured for a given amplitude and frequency change in power supply voltage and is expressed in decibels.

### THEORY OF OPERATION

The AD5780 is a high accuracy, fast settling, single, 18-bit, serial input, voltage output DAC. It operates from a  $V_{\rm DD}$  supply voltage of 7.5 V to 16.5 V and a  $V_{\rm SS}$  supply of –16.5 V to –2.5 V. Data is written to the AD5780 in a 24-bit word format via a 3-wire serial interface. The AD5780 incorporates a power-on reset circuit that ensures the DAC output powers up to 0 V with the  $V_{\rm OUT}$  pin clamped to AGND through a ~6 k $\Omega$  internal resistor.

#### **DAC ARCHITECTURE**

The architecture of the AD5780 consists of two matched DAC sections. A simplified circuit diagram is shown in Figure 49. The six MSBs of the 18-bit data-word are decoded to drive 63 switches, E0 to E62. Each of these switches connects one of 63 matched resistors to either the buffered  $V_{\text{REFP}}$  or buffered  $V_{\text{REFN}}$  voltage. The remaining 12 bits of the data-word drive the S0 to S11 switches of a 12-bit voltage mode R-2R ladder network.

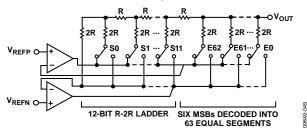

Figure 49. DAC Ladder Structure Serial Interface

#### **SERIAL INTERFACE**

The AD5780 has a 3-wire serial interface (SYNC, SCLK, and SDIN) that is compatible with SPI, QSPI, and MICROWIRE interface standards, as well as most DSPs (see Figure 2 for a timing diagram).

#### **Input Shift Register**

The input shift register is 24 bits wide. Data is loaded into the device MSB first as a 24-bit word under the control of a serial clock input, SCLK, which can operate at up to 35 MHz. The input register consists of a  $R/\overline{W}$  bit, three address bits, and 20 data bits as shown in Table 6. The timing diagram for this operation is shown in Figure 2.

<sup>1</sup> X is don't care.

#### **Standalone Operation**

The serial interface works with both a continuous and noncontinuous serial clock. A continuous SCLK source can be used only if SYNC is held low for the correct number of clock cycles.

In gated clock mode, a burst clock containing the exact number of clock cycles must be used, and \$\overline{SYNC}\$ must be taken high after the final clock to latch the data. The first falling edge of \$\overline{SYNC}\$ starts the write cycle. Exactly 24 falling clock edges must be applied to SCLK before \$\overline{SYNC}\$ is brought high again. If \$\overline{SYNC}\$ is brought high before the 24th falling SCLK edge, the data written is invalid. If more than 24 falling SCLK edges are applied before \$\overline{SYNC}\$ is brought high, the input data is also invalid.

The input shift register is updated on the <u>rising</u> edge of <u>SYNC</u>. For another serial transfer to take place, <u>SYNC</u> must be brought low again. After the end of the serial data transfer, data is automatically transferred from the input shift register to the addressed register. When the write cycle is <u>complete</u>, the output can be updated by taking <u>LDAC</u> low while <u>SYNC</u> is high.

#### Readback

The contents of all the on-chip registers can be read back via the SDO pin. Table 7 outlines how the registers are decoded. After a register has been addressed for a read, the next 24 clock cycles clock the data out on the SDO pin. The clocks must be applied while SYNC is low. When SYNC is returned high, the SDO pin is placed in tristate. For a read of a single register, the NOP function can be used to clock out the data. Alternatively, if more than one register is to be read, the data of the first register to be addressed can be clocked out at the same time that the second register to be read is being addressed. The SDO pin must be enabled to complete a readback operation. The SDO pin is enabled by default.

#### **HARDWARE CONTROL PINS**

#### Load DAC Function (LDAC)

After data has been transferred into the input register of the DAC, there are two ways to update the DAC register and DAC output. Depending on the status of both SYNC and LDAC, one of two update modes is selected: synchronous DAC update or asynchronous DAC update.

#### Synchronous DAC Update

In this mode,  $\overline{\text{LDAC}}$  is held low while data is being clocked into the input shift register. The DAC output is updated on the rising edge of  $\overline{\text{SYNC}}$ .

#### Asynchronous DAC Update

In this mode,  $\overline{\text{LDAC}}$  is held high while data is being clocked into the input shift register. The DAC output is asynchronously updated by taking  $\overline{\text{LDAC}}$  low after  $\overline{\text{SYNC}}$  has been taken high. The update now occurs on the falling edge of  $\overline{\text{LDAC}}$ .

#### Reset Function (RESET)

The AD5780 can be reset to its power-on state by two means: either by asserting the  $\overline{RESET}$  pin or by using the reset function in the software control register (see Table 13). If the  $\overline{RESET}$  pin is not used, hardwire it to IOV<sub>CC</sub>.

#### Asynchronous Clear Function (CLR)

The  $\overline{\text{CLR}}$  pin is an active low clear that allows the output to be cleared to a user defined value. The 18-bit clearcode value is programmed to the clearcode register (see Table 12). It is necessary to maintain  $\overline{\text{CLR}}$  low for a minimum amount of time to complete the operation (see Figure 2). When the  $\overline{\text{CLR}}$  signal is returned high, the output remains at the clear value (if  $\overline{\text{LDAC}}$  is high) until a new value is loaded to the DAC register. The output cannot be updated with a new value while the  $\overline{\text{CLR}}$  pin is low. A clear operation can also be performed by setting the CLR bit in the software control register (see Table 13).

#### **ON-CHIP REGISTERS**

#### **DAC Register**

Table 9 outlines how data is written to and read from the DAC register.

The following equation describes the ideal transfer function of the DAC:

$$V_{OUT} = \frac{\left(V_{REFP} - V_{REFN}\right) \times D}{2^{18}} + V_{REFN}$$

where:

 $V_{REFN}$  is the negative voltage applied at the V<sub>REFN</sub> input pin.  $V_{REFP}$  is the positive voltage applied at the V<sub>REFP</sub> input pin. D is the 18-bit code programmed to the DAC.

#### **Control Register**

The control register controls the mode of operation of the AD5780.

#### **Clearcode Register**

The clearcode register sets the value to which the DAC output is set when the  $\overline{CLR}$  pin or CLR bit in the software control register is asserted. The output value depends on the DAC coding that is being used, either binary or twos complement. The default register value is 0.

#### **Table 10. Control Register**

**Table 11. Control Register Functions** 

| Bit Name | Description   |  |  |  |  |  |
|----------|---|--|--|--|--|--|
| Reserved | These bits are reserved and should be programmed to zero.   |  |  |  |  |  |
| RBUF     | Output amplifier configuration control.   |  |  |  |  |  |
|          | 0: the internal amplifier, A1, is powered up and Resistors R <sub>FB</sub> and R1 are connected in series as shown in Figure 52. This allows an external amplifier to be connected in a gain of two configuration. See the AD5780 Features section for further details.   |  |  |  |  |  |
|          | 1: (default) the internal amplifier, A1, is powered down and Resistors $R_{FB}$ and R1 are connected in parallel, as shown in Figure 51, so that the resistance between the $R_{FB}$ and INV pins is 3.4 k $\Omega$ , equal to the resistance of the DAC. This allows the $R_{FB}$ and INV pins to be used for input bias current compensation for an external unity-gain amplifier. See the AD5780 Features section for further details. |  |  |  |  |  |
| OPGND    | Output ground clamp control.  |  |  |  |  |  |
|          | 0: the DAC output clamp to ground is removed, and the DAC is placed in normal mode.   |  |  |  |  |  |
|          | 1: (default) the DAC output is clamped to ground through a $\sim$ 6 k $\Omega$ resistance, and the DAC is placed in tristate mode. Resetting the part puts the DAC in OPGND mode, where the output ground clamp is enabled and the DAC is tristated. Setting the OPGND bit to 1 in the control register overrules any write to the DACTRI bit   |  |  |  |  |  |
| DACTRI   | DAC tristate control.   |  |  |  |  |  |
|          | 0: the DAC is in normal operating mode.   |  |  |  |  |  |
|          | 1: (default) the DAC is in tristate mode.   |  |  |  |  |  |
| BIN/2sC  | DAC register coding selection.  |  |  |  |  |  |
|          | 0: (default) the DAC register uses twos complement coding.  |  |  |  |  |  |
|          | 1: the DAC register uses offset binary coding.  |  |  |  |  |  |
| SDODIS   | SDO pin enable/disable control.   |  |  |  |  |  |
|          | 0: (default) the SDO pin is enabled.  |  |  |  |  |  |
|          | 1: the SDO pin is disabled (tristate).  |  |  |  |  |  |
| R/W      | Read/write select bit.  |  |  |  |  |  |
|          | 0: AD5780 is addressed for a write operation.   |  |  |  |  |  |
|          | 1: AD5780 is addressed for a read operation.  |  |  |  |  |  |

| 0    | 1                | 0    | 0    | Reserved                       | Reset | CLR <sup>1</sup> | LDAC <sup>2</sup> |

 $<sup>^{1}</sup>$  The CLR function has no effect when the  $\overline{\text{LDAC}}$  pin is low.

**Table 14. Software Control Register Functions** 

| Bit Name | Description  |
|----------|--|
| LDAC     | Setting this bit to 1 updates the DAC register and consequently the DAC output.  |
| CLR      | Setting this bit to 1 sets the DAC register to a user defined value (see Table 12) and updates the DAC output. The output value depends on the DAC register coding that is being used, either binary or twos complement. |
| Reset    | Setting this bit to 1 returns the AD5780 to its power-on state.  |

 $<sup>^{2}\,\</sup>text{The LDAC}$  function has no effect when the  $\overline{\text{CLR}}\,\text{pin}$  is low.

## **AD5780 FEATURES**

#### **POWER-ON TO 0 V**

The AD5780 contains a power-on reset circuit that, as well as resetting all registers to their default values, controls the output voltage during power-up. Upon power-on, the DAC is placed in tristate (its reference inputs are disconnected), and its output is clamped to AGND through a  $\sim$ 6 k $\Omega$  resistor. The DAC remains in this state until programmed otherwise via the control register. This is a useful feature in applications where it is important to know the state of the DAC output while it is in the process of powering up.

#### **CONFIGURING THE AD5780**

After power-on, the AD5780 must be configured to put it into normal operating mode before programming the output. To do this, the control register must be programmed. The DAC is removed from tristate by clearing the DACTRI bit, and the output clamp is removed by clearing the OPGND bit. At this point, the output goes to  $V_{\text{REFN}}$  unless an alternative value is first programmed to the DAC register.

#### **DAC OUTPUT STATE**

The DAC output can be placed in one of three states, controlled by the DACTRI and OPGND bits of the control register, as shown in Table 15.

Table 15. Output State Truth Table

| DACTRI | OPGND | Output State                                       |
|--------|-------|--|
| 0      | 0     | Normal operating mode.                             |
| 0      | 1     | Output is clamped via $\sim$ 6 k $\Omega$ to AGND. |
| 1      | 0     | Output is in tristate.                             |
| 1      | 1     | Output is clamped via $\sim$ 6 k $\Omega$ to AGND. |

#### **OUTPUT AMPLIFIER CONFIGURATION**

There are a number of different ways that an output amplifier can be connected to the AD5780, depending on the voltage references applied and the desired output voltage span.

#### **Unity-Gain Configuration**

Figure 50 shows an output amplifier configured for unity gain. In this configuration, the output spans from  $V_{\text{REFN}}$  to  $V_{\text{REFP}}$ .

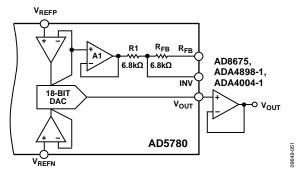

Figure 50. Output Amplifier in Unity-Gain Configuration

A second unity-gain configuration for the output amplifier is one that removes an offset from the input bias currents of the amplifier. It does this by inserting a resistance in the feedback path of the amplifier that is equal to the output resistance of the DAC. The DAC output resistance is 3.4 k $\Omega$ . By connecting R1 and R<sub>FB</sub> in parallel, a resistance equal to the DAC resistance is available on chip. Because the resistors are all on one piece of silicon, they are temperature coefficient matched. To enable this mode of operation, the RBUF bit of the control register must be set to Logic 1. Figure 51 shows how the output amplifier is connected to the AD5780. In this configuration, the output amplifier is in unity gain and the output spans from  $V_{REFN}$  to  $V_{REFP}$ . This unity-gain configuration allows a capacitor to be placed in the amplifier feedback path to improve dynamic performance.

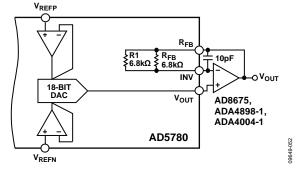

Figure 51. Output Amplifier in Unity Gain with Amplifier Input Bias Current Compensation

#### Gain of Two Configuration (×2 Gain Mode)

Figure 52 shows an output amplifier configured for a gain of two. The gain is set by the internal matched 6.8 k $\Omega$  resistors, which are exactly twice the DAC resistance, having the effect of removing an offset from the input bias current of the external amplifier. In this configuration, the output spans from 2 × V\_REFN – V\_REFP to V\_REFP. This configuration is used to generate a bipolar output span from a single-ended reference input, with V\_REFN = 0 V. For this mode of operation, the RBUF bit of the control register must be cleared to Logic 0.

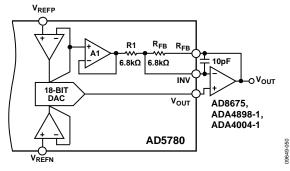

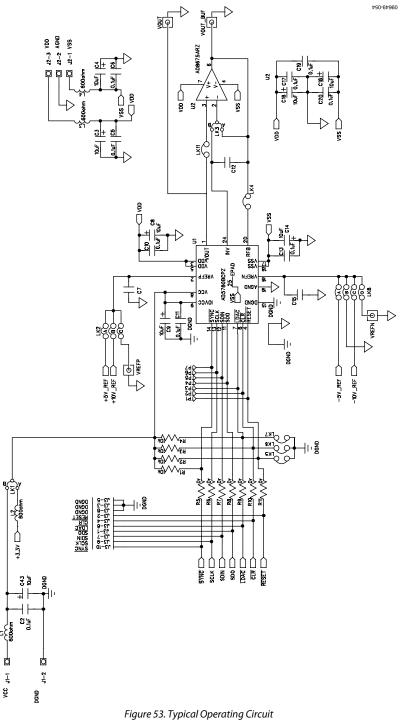

Figure 52. Output Amplifier in Gain-of-Two Configuration

## **APPLICATIONS INFORMATION TYPICAL OPERATING CIRCUIT**

Figure 53 shows a typical operating circuit for the AD5780 using an AD8675 as an output buffer. Because the output impedance of the AD5780 is 3.4  $k\Omega,$  an output buffer is required for driving low resistive, high capacitive loads.

#### **EVALUATION BOARD**

An evaluation board is available for the AD5780 to aid designers in evaluating the high performance of the part with minimum effort. The AD5780 evaluation kit includes a populated and tested AD5780 printed circuit board (PCB). The evaluation board interfaces to the USB port of a PC. Software is available

with the evaluation board to allow the user to easily program the AD5780. The software runs on any PC that has Microsoft\* Windows\* XP (SP2), Vista (32-bit or 64-bit), or Windows 7 installed. The AD5780 user guide, UG-256, is available, which gives full details on the operation of the evaluation board.
