HEDS-9200 Series
Linear Optical Incremental Encoder Modules

Data Sheet

Description

The HEDS-9200 series is a high performance, low cost, optical incremental encoder module. When operated in conjunction with a codestrip, this module detects linear position. The module consists of a lensed LED source and a detector IC enclosed in a small C-shaped plastic package. Due to a highly collimated light source and a unique photodetector array, the module is extremely tolerant to mounting misalignment.

The two channel digital outputs and the single 5 V supply input are accessed through four 0.025 inch square pins located on 0.1 inch centers.

Five standard resolutions between 4.72 counts per mm (120 counts per inch) and 7.87 counts per mm (200 counts per inch) are available. Consult local Avago sales representatives for other resolutions ranging from 1.5 to 7.87 counts per mm (40 to 200 counts per inch).

Features

- High performance
- High resolution
- Low cost
- Easy to mount
- No signal adjustment required
- Insensitive to mechanical disturbances
- Small size
- -40° C to 100° C operating temperature
- Two channel quadrature output
- TTL compatible
- Single 5 V supply

Package Dimensions

Note: Codestrip not included with HEDS-9200

ESD WARNING: Normal handling precautions should be taken to avoid static discharge.
Definitions

Count density (D): The number of bar and window pairs per unit length of the codestrip.

Pitch: 1/D, The unit length per count.

Electrical degree (°e): Pitch/360, The dimension of one bar and window pair divided by 360.

1 cycle (C): 360 electrical degrees, 1 bar and window pair.

Pulse Width (P): The number of electrical degrees that an output is high during 1 cycle. This value is nominally 180°e or ½ cycle.

Pulse Width Error (ΔP): The deviation, in electrical degrees, of the pulse width from its ideal value of 180°e.

State Width (S): The number of electrical degrees between a transition in the output of channel A and the neighboring transition in the output of channel B. There are 4 states per cycle, each nominally 90°e.

State Width Error (ΔS): The deviation, in electrical degrees, of each state width from its ideal value of 90°e.

Phase (φ): The number of electrical degrees between the center of the high state of channel A and the center of the high state of channel B. This value is nominally 90°e for quadrature output.

Phase Error (Δφ): The deviation of the phase from its ideal value of 90°e.

Direction of Movement: When the codestrip moves, relative to the module, in the direction of the arrow on top of the module, channel A will lead channel B. If the codestrip moves in the opposite direction, channel B will lead channel A.

Applications

The HEDS-9200 provides sophisticated motion detection at a low cost, making it ideal for high volume applications. Typical applications include printers, plotters, tape drives, and factory automation equipment.

Note: Avago Technologies encoders are not recommended for use in safety critical applications. Eg. ABS braking systems, power steering, life support systems and critical care medical equipment. Please contact sales representative if more clarification is needed.

Theory of Operation

The HEDS-9200 is a C-shaped emitter/detector module. Coupled with a codestrip it translates linear motion into a two-channel digital output.

As seen in the block diagram, the module contains a single Light Emitting Diode (LED) as its light source. The light is collimated into a parallel beam by means of a single polycarbonate lens located directly over the LED. Opposite the emitter is the integrated detector circuit. This IC consists of multiple sets of photodetectors and the signal processing circuitry necessary to produce the digital waveforms.

The codestrip moves between the emitter and detector, causing the light beam to be interrupted by the pattern of spaces and bars on the codestrip. The photodiodes which detect these interruptions are arranged in a pattern that corresponds to the count density of the codestrip. These detectors are also spaced such that a light period on one pair of detectors corresponds to a dark period on the adjacent pair of detectors. The photodiode outputs are then fed through the signal processing circuitry resulting in A, Ā, B and Ā. Two comparators receive these signals and produce the final outputs for channels A and B. Due to this integrated phasing technique, the digital output of channel A is in quadrature with that of channel B (90 degrees out of phase).

Note:
1. For improved performance in noisy environments or high speed applications, a 3.3 kΩ pull-up resistor is recommended.
Derating Curves over Extended Operating Frequencies (HEDS-9200 Series)

Below are the derating curves for state, duty, phase and \( V_{OH} \) over extended operating frequencies of up to 240 kHz (recommended maximum frequency is 100 kHz). The curves were derived using standard TTL load. -40°C operation is not feasible above 160 kHz because \( V_{OH} \) will drop below 2.4 V (the minimum TTL for logic state high) beyond that frequency.
Recommended Codestrip Characteristics

Codestrip design must take into consideration mounting as referenced to either side A or side B (see Figure 4).

Note: All parameters and equations must be satisfied over the full length of codestrip travel including maximum codestrip runout.

STATIC CHARGE WARNING: Large static charge on codestrip may harm module. Prevent accumulation of charge.

Figure 1. Codestrip Design.
Mounting Considerations

Notes:
1. These dimensions include codestrip warp.
2. Reference definitions of La and Lb on page 4.
3. Maximum recommended mounting screw torque is 4 kg-cm (3.5 in-lbs).
4. * For window option measurement = 3.22 (0.127).
