## MAX77659

## SIMO PMIC with 300mA Switching Charger

### General Description

The MAX77659 provides highly-efficient integrated battery charging and power supply solutions for low-power applications where size and efficiency are critical. The IC features a dual-input SIMO buck-boost regulator that provides one charging rail and three independently programmable power rails from a single inductor to minimize total solution size. A 100mA LDO provides ripple rejection for audio and other noise-sensitive applications. The LDO can also be configured as a load switch to manage power consumption by disconnecting external blocks when not required. A highly-configurable switching charger supports a wide range of Li+ battery capacities and includes battery temperature monitoring for additional safety (JEITA).

This device includes two GPIOs and an analog multiplexer that switches several internal voltages and current signals to an external node for monitoring with an external ADC. A bidirectional I<sup>2</sup>C serial interface allows for configuring and checking the status of the devices. An internal on/off controller provides a controlled startup sequence for the regulators and provides supervisory functionality while they are on. Numerous factory programmable options allow the device to be tailored for many applications, enabling faster time to market.

### Applications

- TWS Earbuds
- Bluetooth Headphones, Hearables
- Smart Wearables, Fitness Bands, and Medical Wearables
- Hearing Aids

### Benefits and Features

- Highly Integrated
  - 3x Output, Single-Inductor Multiple-Output (SIMO) Buck-Boost Regulator
    - Supports Wide Output Voltage Range from 0.5V to 5.5V for all SIMO Channels
  - 1x 100mA LDO/LSW
  - Smart Power Selector™ Li+/Li-Poly Switching Charger
  - 2x GPIO Resources
  - Analog MUX Output for Power Monitoring
  - Factory-Ship Mode (< 200nA I<sub>Q</sub>)
  - Watchdog Timer
- Low Power
  - 0.3µA Shutdown Current
  - 5µA Operating Current (3 SIMO Channels + 1 LDO)
- Charger Optimized for Small Battery Size
  - Input Operating Voltage from 3.4V to 5.5V
  - Programmable Fast-Charge Current from 7.5mA to 300mA
  - Programmable Battery Regulation Voltage from 3.6V to 4.6V
  - Programmable Termination Current from 0.375mA to 45mA
  - Thermal Regulation and JEITA Compliance
- Flexible and Configurable
  - I<sup>2</sup>C-Compatible Interface and GPIO
  - Factory OTP Options Available
- Small Size
  - 6.04mm<sup>2</sup> Wafer-Level Package (WLP)
  - 30-Bump, 0.4mm Pitch, 6x5 Array

[Ordering Information](#) appears at end of data sheet.

## Absolute Maximum Ratings

nIRQ, nRST to GND	-0.3V to $V_{AVL} + 0.3V$	$V_{IO}$ to GND	-0.3V to $V_{AVL} + 6V$
nEN to GND (Note 1)	-0.3V to $V_{CCINT} + 0.3V$	IN_SBB to PGND	-0.3V to +6.0V
SCL, SDA, GPIO to GND	-0.3V to $V_{IO} + 0.3V$	LXA Continuous Current (Note 3)	1.2A <sub>RMS</sub>
CHGIN to PGND	-0.3V to +6.0V	LXB Continuous Current (Note 3)	1.2A <sub>RMS</sub>
SYS, BATT to GND	-0.3V to +6.0V	SBB0, SBB1, SBB2 to PGND	-0.3V to +6.0V
SYS to IN_SBB	-0.3V to +0.3V	BST to PVL	-0.3V to +6.0V
AVL to GND	-0.3V to +6.0V	BST to LXB	-0.3V to +6.0V
PVL to PGND	-0.3V to +6.0V	SBB0, SBB1, SBB2, SBB3 Short-Circuit Duration	Continuous
AMUX, THM, TBIAS to GND	-0.3V to $V_{AVL} + 0.3V$	PGND to GND	-0.3V to +0.3V
nIRQ, nRST, SDA, AMUX, GPIO Continuous Current	±20mA	Operating Temperature Range	-40°C to +85°C
CHGIN Continuous Current	1.2A <sub>RMS</sub>	Junction Temperature	+150°C
SYS Continuous Current	1.2A <sub>RMS</sub>	Storage Temperature Range	-65°C to +150°C
BATT Continuous Current (Note 2)	1.2A <sub>RMS</sub>	Soldering Temperature (reflow)	+260°C
IN_LDO to GND	-0.3V to 6V	Continuous Power Dissipation (Multilayer Board, $T_A = +70^\circ\text{C}$ , derate 20.4mW/°C above +70°C)	1632mW
LDO to GND	-0.3V to $V_{IN\_LDO} + 0.3V$		

**Note 1:**  $V_{CCINT}$  is internally connected to either BATT or CHGIN. See the [nEN Internal Pullup Resistors to  \$V\_{CCINT}\$](#)  section for more details.

**Note 2:** Do not repeatedly hot-plug a source to the BATT terminal at a rate greater than 10Hz. Hot plugging low impedance sources results in an ~8A momentary (~2μs) current spike.

**Note 3:** Do not externally bias LXA or LXB. LXA has internal clamping diodes to PGND and IN\_SBB. LXB has an internal low-side clamping diode to PGND and an internal high-side clamping diode that dynamically connects to a selected SIMO output. It is normal for these diodes to briefly conduct during switching events. When the SIMO regulator is disabled, the LXB to PGND absolute maximum voltage is -0.3V to  $V_{SBB0} + 0.3V$ .

*Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.*

## Package Information

### WLP

Package Code	N302D2+1
Outline Number	<a href="#">21-100509</a>
Land Pattern Number	Refer to <a href="#">Application Note 1891</a>
<b>Thermal Resistance, Four-Layer Board:</b>	
Junction to Ambient ( $\theta_{JA}$ )	49°C/W (2s2p board)

- DRAWING NOT TO SCALE -

For the latest package outline information and land patterns (footprints), go to [www.maximintegrated.com/packages](http://www.maximintegrated.com/packages). Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to [www.maximintegrated.com/thermal-tutorial](http://www.maximintegrated.com/thermal-tutorial).

## Electrical Characteristics

( $V_{CHGIN} = 0V$ ,  $V_{SYS} = V_{BATT} = V_{IN\_SBB} = V_{IN\_LDO} = 3.7V$ ,  $V_{IO} = 1.8V$ , limits are 100% production tested at  $T_A = +25^\circ C$ . Limits over the operating temperature range ( $T_A = -40^\circ C$  to  $+85^\circ C$ ) are guaranteed by design and characterization, unless otherwise noted.)

PARAMETER	SYMBOL	CONDITIONS		MIN	TYP	MAX	UNITS
Operating Voltage Range	$V_{SYS}$			2.7		5.5	V
Shutdown Supply Current	$I_{SHDN}$	Current measured into BATT and SYS and IN_SBB and IN_LDO, all resources are off (LDO, SBB0, SBB1, SBB2), $T_A = +25^\circ C$	Main bias is off (CNFG_GLBL.SBIA_EN = 0); this is the standby state		0.3	1	$\mu A$
			Main bias is on in low-power mode (CNFG_GLBL.SBIA_EN = 1, CNFG_GLBL.SBIA_LPM = 1)		1		
			Main bias is on in normal-power mode (CNFG_GLBL.SBIA_EN = 1, CNFG_GLBL.SBIA_LPM = 0)		28		
Main Bias Quiescent Current	$I_Q$	Main bias is in normal-power mode (CNFG_GLBL.SBIA_LPM = 0)			28		$\mu A$
Quiescent Supply Current	$I_Q$	Current measured into BATT and SYS and IN_SBB and IN_LDO; LDO, SBB0, SBB1, SBB2 are enabled with no load watchdog timer disabled	Main bias is in low-power mode (CNFG_GLBL.SBIA_LPM = 1)		6	13	$\mu A$
BATT Factory-Ship Mode Current	$I_{BATT-FSM}$	Factory-ship mode (BATT to SYS switch open), $T_A = +25^\circ C$ , $V_{BATT} = 3.7V$ , $V_{SYS} = V_{INLDO} = 0V$			0.2	1	$\mu A$

## Electrical Characteristics—Global Resources

( $V_{AVL} = 3.7V$ , limits are 100% production tested at  $T_A = +25^\circ C$ , limits over the operating temperature range ( $T_A = -40^\circ C$  to  $+85^\circ C$ ) are guaranteed by design and characterization, unless otherwise noted.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
<b>GENERAL CHARACTERISTICS</b>						
Main Bias Enable Time	$t_{SBIA\_EN}$			0.5		ms
<b>VOLTAGE MONITORS / POWER-ON RESET (POR)</b>						
POR Threshold	$V_{POR}$	$V_{AVL}$ falling	1.6	1.9	2.1	V
POR Threshold Hysteresis				100		mV
<b>VOLTAGE MONITORS / UNDERVOLTAGE LOCKOUT (UVLO)</b>						
UVLO Threshold	$V_{AVLUVLO}$	$V_{AVL}$ falling	2.5	2.6	2.7	V

### Electrical Characteristics—Global Resources (continued)

( $V_{AVL} = 3.7V$ , limits are 100% production tested at  $T_A = +25^\circ C$ , limits over the operating temperature range ( $T_A = -40^\circ C$  to  $+85^\circ C$ ) are guaranteed by design and characterization, unless otherwise noted.)

PARAMETER	SYMBOL	CONDITIONS		MIN	TYP	MAX	UNITS
UVLO Threshold Hysteresis	$V_{AVLUVLO\_HYS}$				300		mV
<b>VOLTAGE MONITORS / OVERVOLTAGE LOCKOUT (OVLO)</b>							
OVLO Threshold	$V_{SYSOVLO}$	$V_{SYS}$ rising		5.70	5.85	6.00	V
<b>THERMAL MONITORS</b>

		CHGIN is valid, CNFG_SBB_TOP_B.IP_SBB3[1:0] = 0b01		1.500			
		CHGIN is valid, CNFG_SBB_TOP_B.IP_SBB3[1:0] = 0b00		2.000			

**Note 5:** Typical values align with bench observations using the stated conditions with an inductor. Minimum and maximum values are tested in production with DC currents without an inductor. See the [Typical Operating Characteristics](#) SIMO switching waveforms to gain more insight on this specification.

## Electrical Characteristics—Smart Power Selector Charger

( $V_{CHGIN} = 5.0V$ ,  $V_{BATT} = 4.2V$ , limits are 100% production tested at  $T_A = +25^\circ C$ , limits over the operating temperature range ( $T_A = -40^\circ C$  to  $+85^\circ C$ ) are guaranteed by design and characterization, unless otherwise noted.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
<b>DC INPUT</b>						
CHGIN Valid Voltage Range	$V_{CHGIN}$	Initial CHGIN voltage before enabling charging	3.4		5.5	V
CHGIN Overvoltage Threshold	$V_{CHGIN\_OVP}$	DC rising	5.5	5.65	5.8	V
CHGIN Overvoltage Hysteresis				100		mV
CHGIN Undervoltage Lockout	$V_{CHGIN\_UVLO}$	DC rising	3.2	3.3	3.4	V
CHGIN Undervoltage-Lockout Hysteresis				200		mV
Charger Input Debounce Timer	$t_{CHGIN-DB}$	$V_{CHGIN} = 5V$ , time before CHGIN is allowed to deliver current to SYS or BATT	100	120	140	ms
<b>SUPPLY AND QUIESCENT CURRENTS</b>						
CHGIN Supply Current	$I_{CHGIN}$	$V_{CHGIN} = 5V$ , charger is not in USB suspend (CNFG_CHG_G.USBS = 0), charging is finished (STAT_CHG_B.CHG_DTLS[3:0] indicates done), $I_{SYS} = 0mA$		1.0	1.8	mA
CHGIN Input Active Discharge Resistance	$R_{AD\_CHGIN}$	$V_{CHGIN} < V_{CHGIN\_UVLO}$	0.66	1	1.7	k $\Omega$
CHGIN Suspend Supply Current	$I_{CHGIN-SUS}$	$V_{CHGIN} = 5V$ , charger in USB suspend (CNFG_CHG_G.USBS = 1), $V_{BATT} = 4.3V$ , SBB0/1/2 and LDO are disabled		50		$\mu A$
BATT Bias Current	$I_{BATT-BIAS}$	$V_{CHGIN} = 5V$ , charger is not in USB suspend (CNFG_CHG_G.USBS = 0), charging is finished (STAT_CHG_B.CHG_DTLS[3:0] indicates done), $I_{SYS} = 0mA$		9		$\mu A$
<b>PREQUALIFICATION</b>						
Prequalification Voltage Threshold Range	$V_{PQ}$	Programmable in 100mV steps with CNFG_CHG_C.CHG_PQ[2:0]	2.3		3.0	V
Prequalification Voltage Threshold Accuracy		$V_{PQ} = 3.0V$	-3		+3	%
Prequalification Mode Charge Current	$I_{PQ}$	$V_{BATT} = 2.5V$ $V_{PQ} = 3.0V$ Expressed as a percentage of $I_{FAST-CHG}$	CNFG_CHG_B.I_P Q = 0	10		%
			CNFG_CHG_B.I_P Q = 1	20		
Prequalification Safety Timer	$t_{PQ}$	$V_{BATT} < V_{PQ} = 3.0V$	27	30	33	minutes
<b>FAST-CHARGE</b>						
Fast-Charge Voltage Range	$V_{FAST-CHG}$	$I_{BATT} = 0mA$ , programmable in 25mV steps with CNFG_CHG_G.CHG_CV[5:0]	3.6		4.6	V

### Electrical Characteristics—Smart Power Selector Charger (continued)

( $V_{CHGIN} = 5.0V$ ,  $V_{BATT} = 4.2V$ , limits are 100% production tested at  $T_A = +25^\circ C$ , limits over the operating temperature range ( $T_A = -40^\circ C$  to  $+85^\circ C$ ) are guaranteed by design and characterization, unless otherwise noted.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS	
Fast-Charge Voltage Accuracy		$I_{BATT} = 0mA$	$V_{FAST-CHG} = 4.3V$ , $V_{SYS} = V_{FAST-CHG} + 200mV$ , $T_A = +25^\circ C$	-0.5		+0.5	%
			$V_{FAST-CHG} = 3.6V$ to $4.6V$ , $V_{SYS} = V_{FAST-CHG} + 200mV$			1.0	
Fast-Charge Current Range	$I_{FAST-CHG}$	Programmable in 7.5mA steps with CNFG_CHG_E.CHG_CC[5:0]	7.5		300	mA	
Fast-Charge Current Accuracy		$T_A = +25^\circ C$ , $V_{BATT} = V_{FAST-CHG} - 300mV$	$I_{FAST-CHG} = 15mA$	-1.5		+1.5	%
			$I_{FAST-CHG} = 300mA$	-2.0		+2.0	
Fast-Charge Current Accuracy over Temperature		Across all current settings, $V_{BATT} = V_{FAST-CHG} - 300mV$ , $T_A = -40^\circ C$ to $+85^\circ C$	-10		+10	%	
Fast-Charge Safety Timer Range	$t_{FC}$	Programmable in 2 hour increments or disabled with CNFG_CHG_E.T_FAST_CHG[1:0], time measured from prequal. done to timer fault	3		7	hours	
Fast-Charge Safety Timer Accuracy		$t_{FC} = 3$ hours	-10		+10	%	
Fast-Charge Safety Timer Suspend Threshold		Fast-charge CC mode, fast-charge safety timer paused when charge current drops below this threshold, expressed as a percentage of $I_{FAST-CHG}$		20		%	
Junction Temperature Regulation Setting Range	$T_{J-REG}$	Programmable in $10^\circ C$ steps with CNFG_CHG_D.TJ_REG[2:0]	60		100	$^\circ C$	
Junction Temperature Regulation Loop Gain	$G_{TJ-REG}$	Rate at which $I_{FAST-CHG}/I_{PQ}$ is reduced to maintain $T_{J-REG}$ , expressed as a percentage of $I_{FAST-CHG}/I_{PQ}$ per degree centigrade rise		-5.4		$\%/^\circ C$	
Charge Current Soft-Start Slew Time		Zero to full-scale		1		ms	
<b>TERMINATION AND TOP-OFF</b>							
End-of-Charge Termination Current	$I_{TERM}$	CNFG_CHG_C.I_TERM[1:0] = 0b00 expressed as a percentage of $I_{FAST-CHG}$		5		%	
		CNFG_CHG_C.I_TERM[1:0] = 0b01 expressed as a percentage of $I_{FAST-CHG}$		7.5			
		CNFG_CHG_C.I_TERM[1:0] = 0b10 expressed as a percentage of $I_{FAST-CHG}$	8.5	10	11.5		
		CNFG_CHG_C.I_TERM[1:0] = 0b11 expressed as a percentage of $I_{FAST-CHG}$		15			

### Electrical Characteristics—Smart Power Selector Charger (continued)

( $V_{CHGIN} = 5.0V$ ,  $V_{BATT} = 4.2V$ , limits are 100% production tested at  $T_A = +25^\circ C$ , limits over the operating temperature range ( $T_A = -40^\circ C$  to  $+85^\circ C$ ) are guaranteed by design and characterization, unless otherwise noted.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
Top-Off Timer Range	$t_{TO}$	$I_{BATT} < I_{TERM}$ , programmable in 5 minute steps with CNFG_CHG_C.T_TOPOFF[2:0]	0		35	minutes
Top-Off Timer Accuracy		$t_{TO} = 10$ minutes	-10		+10	%
Charge Restart Threshold	$V_{RESTART}$	Charging is finished (STAT_CHG_B.CHG_DTLS[3:0] indicates done) Charging resumes when $V_{BATT} < V_{FAST-CHG} - V_{RESTART}$	50	100		mV
End-of-Charge Termination Current Accuracy		$I_{FAST-CHG} = 15mA$ , $I_{TERM} = 1.5mA$ (10% of $I_{FAST-CHG}$ ), $T_A = +25^\circ C$	1.35	1.5	1.65	mA
		$I_{FAST-CHG} = 300mA$ , $I_{TERM} = 30mA$ (10% of $I_{FAST-CHG}$ ), $T_A = +25^\circ C$	27	30	33	
End-of-Charge Termination Current Glitch Filter				60		$\mu s$
<b>DEVICE ON-RESISTANCE AND LEAKAGE</b>						
BATT to SYS On-Resistance		$V_{BATT} = 3.7V$ , $I_{BATT} = 300mA$ , $V_{CHGIN} = 0V$ , battery is discharging to SYS		100	150	m $\Omega$
Charger FET Leakage Current		$V_{CHGIN} = 5V$ , $V_{SYS} = V_{SBB3} = 4.5V$ , $V_{BATT} = 0V$ , charger disabled	$T_A = +25^\circ C$	0.1	1.0	$\mu A$
			$T_A = +85^\circ C$	1		
<b>SYSTEM NODE</b>

Pin Configuration

MAX77659xENV

Pin Description

PIN	NAME	FUNCTION	TYPE
<b>TOP LEVEL</b>			
C6	V <sub>IO</sub>	I <sup>2</sup> C Interface and GPIO Driver Power	Power Input
B6	nEN	Active-Low Enable Input. $\overline{EN}$ supports push-button or slide-switch configurations. If not used, connect $\overline{EN}$ to SYS and use the CNFG_SBBx_B.EN_SBBx[2:0] and CNFG_LDOx_B.EN_LDO[2:0] bitfields to enable channels. Pulled up internally to V <sub>CCINT</sub> .	Digital Input
C5	nIRQ	Active-Low, Open-Drain Interrupt Output. Connect a 100kΩ pullup resistor between $\overline{IRQ}$ and a voltage equal to or less than V <sub>SYS</sub> .	Digital Output
B5	nRST	Active-Low, Open-Drain Reset Output. Connect a 100kΩ pullup resistor between $\overline{RST}$ and a voltage equal to or less than V <sub>SYS</sub> .	Digital Output
A5	GPIO0	General Purpose Input/Output. The GPIO I/O stage is internally biased with V <sub>IO</sub> .	Digital I/O
A6	GPIO1	General Purpose Input/Output. The GPIO I/O stage is internally biased with V <sub>IO</sub> .	Digital I/O
D5	SCL	I <sup>2</sup> C Clock	Digital Input
D6	SDA	I <sup>2</sup> C Data	Digital I/O
B4	GND	Quiet Ground. Connect GND to PGND, and the low-impedance ground plane of the PCB.	Ground

## Pin Description (continued)

PIN	NAME	FUNCTION	TYPE
<b>CHARGER</b>			
E1	CHGIN	Charger Input. Connect to a DC charging source. Bypass to GND with a 44 $\mu$ F ceramic capacitor as close as possible to the CHGIN pin.	Power Input
B1	SYS	System Power Output. SYS provides power to the system resources. Connect to IN_SBB and SBB3 and bypass to GND with a 22 $\mu$ F ceramic capacitor.	Power Output
A2	AVL	Internal logic supply shorted to the higher of CHGIN and SYS. Bypass to GND with a 1 $\mu$ F ceramic capacitor. Do not load AVL externally.	Power Output
B2	PVL	Power supply for SIMO pre-drivers. Connect to AVL. Do not load PVL externally.	Power Input
A1	BATT	Li+ Battery Connection. Connect to positive battery terminal. Bypass to GND with a 4.7 $\mu$ F ceramic capacitor.	Power I/O
B3	TBIAS	Thermistor Bias Supply. Connect a resistor equal to the NTCs room temperature resistance between TBIAS and THM. Do not load TBIAS with any other external circuitry. If not used, leave the pin disconnected.	Analog
A3	THM	Thermistor Monitor. Thermally couple an NTC to the battery and connect between THM and GND. If not used, connect THM directly to ground.	Analog Input
A4	AMUX	Analog Multiplexer Output. Connect to system ADC to perform conversions on charger power signals.	Analog Output
<b>SIMO BUCK-BOOST</b>			
C2	IN_SBB	SIMO Power Input. Connect IN_SBB to SYS and bypass to PGND with a minimum of 22 $\mu$ F ceramic capacitor as close as possible to the IN_SBB pin.	Power Input
E3	SBB0	SIMO Buck-Boost Output 0. SBB0 is the power output for channel 0 of the SIMO buck-boost. Bypass SBB0 to PGND with a 22 $\mu$ F ceramic capacitor. If not used, see the <a href="#">Unused Outputs</a> section.	Power Output
E4	SBB1	SIMO Buck-Boost Output 1. SBB1 is the power output for channel 1 of the SIMO buck-boost. Bypass SBB1 to PGND with a 22 $\mu$ F ceramic capacitor. If not used, see the <a href="#">Unused Outputs</a> section.	Power Output
C4	SBB2	SIMO Buck-Boost Output 2. SBB2 is the power output for channel 2 of the SIMO buck-boost. Bypass SBB0 to PGND with a 22 $\mu$ F ceramic capacitor. If not used, see the <a href="#">Unused Outputs</a> section.	Power Output
C3	SBB3	SIMO Buck-Boost Output 3. Output only available when CHGIN is present. Connect to SYS and bypass SBB3 to PGND with a 22 $\mu$ F ceramic capacitor.	Power Output
E2	BST	SIMO Power Input for the High-Side Output NMOS Drivers. Connect a 10nF ceramic capacitor between BST and LXB.	Power Input
D1, D2	LXA	Switching Node A. LXA is driven between PGND and IN_SBB when any SIMO channel is enabled. LXA is driven to PGND when all SIMO channels are disabled. Connect a 1.5 $\mu$ H inductor between LXA and LXB.	Power I/O
D3, D4	LXB	Switching Node B. LXB is driven between PGND and SBBx when SBBx is enabled. LXB is driven to PGND when all SIMO channels are disabled. Connect a 1.5 $\mu$ H inductor between LXA and LXB.	Power Input
E1	PGND	Power ground for the SIMO low-side FETs. Connect PGND to GND and the low-impedance ground plane of the PCB.	Ground
<b>LDO</b>			
E5	IN_LDO	Linear Regulator Input. If connected to a SIMO output with a short trace, IN_LDO can share the output's capacitor. Otherwise, bypass with a 2.2 $\mu$ F ceramic capacitor to ground. If not used, connect to ground or leave unconnected.	Power Input
E6	LDO	Linear Regulator Output. Bypass with a 1.0 $\mu$ F ceramic capacitor to GND. If not used, disable LDO and connect this pin to ground or leave unconnected.	Power Output

### Detailed Description

The MAX77659 provides a highly-integrated battery charging and power management solution for low-power applications, especially the TWS earbuds. The switching charger can charge various Li+ batteries with a wide range of charge current and charger termination voltage options while minimizing heat dissipation during the fast-charge process. Temperature monitoring and JEITA compliance settings add additional functionality and safety to the charger.

Four regulators are integrated within this device (see [Table 1](#)). A single-inductor, multiple-output (SIMO) buck-boost regulator efficiently provides three independently programmable power rails. One 100mA low-dropout linear regulator (LDO) provides ripple rejection for audio and other noise-sensitive applications.

This device includes other features such as an analog multiplexer that switches several internal voltages and current signals to an external node for monitoring with an external ADC. A bidirectional I<sup>2</sup>C serial interface allows for configuring and checking the status of the device. An internal on/off controller provides regulator sequencing and supervisory functionality for the device.

**Table 1. Regulator Summary**

REGULATOR NAME	REGULATOR TOPOLOGY	MAXIMUM I <sub>OUT</sub> (mA)	V <sub>IN</sub> RANGE (V)	MAX77659 V <sub>OUT</sub> RANGE/RESOLUTION
SBB0	SIMO	Up to 500*	2.7 to 5.5	0.5V to 1.675V in 25mV steps 1.7V to 5.5V in 50mV steps
SBB1	SIMO		2.7 to 5.5	0.5V to 1.675V in 25mV steps 1.7V to 5.5V in 50mV steps
SBB2	SIMO		2.7 to 5.5	0.5V to 1.675V in 25mV steps 1.7V to 5.5V in 50mV steps
LDO	PMOS LDO	100	1.7 to 5.5	0.5V to 5.0V in 25mV steps

\*Shared capacity with other SBBx channels. See the [SIMO Available Output Current](#) section for more information.

### Part Number Decoding

The MAX77659 has different one-time programmable (OTP) options and variants to support a variety of applications. OTP options set default settings such as output voltage or CHGIN current limit. Variants are versions of MAX77659 with different features. See [Figure 1](#) for how to identify these. [Table 2](#) lists all available OTP options. Refer to the [Maxim Integrated naming convention](#) for more details.

Figure 1. Part Number Decode

Table 2. OTP Options Table

			OTP LETTER AND SETTINGS
BLOCK	BITFIELD NAME	SETTING NAME	A
Global	SBIA_LPM	Bias Low-Power Mode	NPM
	DBEN_nEN	nEN Debounce Time	500µA
	nEN_MODE	nEN Mode	Push-Button
	T_MRST	Manual Reset Time	3.3s
	ALT_GPIO0	GPIO0 Mode	GPIO
	ALT_GPIO1	GPIO1 Mode	GPIO
	ADDR	I <sup>2</sup> C Address (7-bit)	0x40
	CID[4:0]	Chip ID	0x01
Watchdog	WDT_LOCK	Watchdog Timer Disable Control	Unlocked
	WDT_EN	Watchdog Timer Enable	Disabled
SIMO	TV_SBB0[6:0]	SBB0 V <sub>OUT</sub>	1.000V
	IP_SBB0[1:0]	SBB0 Peak Inductor Current Limit	0.500A
	OP_MODE (SBB0)	SBB0 Operating Mode	Buck
	ADE_SBB0	Active-Discharge Resistor Enable	Enabled
	EN_SBB0[2:0]	SBB0 Enable Control	FPS Slot 1
	TV_SBB1[6:0]	SBB1 V <sub>OUT</sub>	1.800V
	IP_SBB1[1:0]	SBB1 Peak Inductor Current Limit	0.500A
	OP_MODE (SBB1)	SBB1 Operating Mode	Buck
	ADE_SBB1	Active-Discharge Resistor Enable	Enabled
	EN_SBB1[2:0]	SBB1 Enable Control	On
	TV_SBB2[6:0]	SBB2 V <sub>OUT</sub>	4.500V
	IP_SBB2[1:0]	SBB2 Peak Inductor Current Limit	1.000A
	OP_MODE (SBB2)	SBB2 Operating Mode	Buck-Boost
	ADE_SBB2	Active-Discharge Resistor Enable	Enabled
EN_SBB2[2:0]	SBB2 Enable Control	FPS Slot 0	
LDO	TV_LDO[7:0]	LDO V <sub>OUT</sub>	1.800V
	LDO_MD	LDO or LSW Mode	LDO
	ADE_LDO0	Active-Discharge Resistor Enable	Enabled
	EN_LDO[2:0]	LDO Enable Control	FPS Slot 3
Charger	CHG_EN	Charger Enable	Disabled
	IP_CHG[1:0]	SBB3_CHG Peak Inductor Current Limit	1.000A

## Support Material

The following support materials are available for this device:

- MAX77659 [Register Map](#): Full table of registers that can be read from or written to by I<sup>2</sup>C.
- MAX77659 [SIMO Calculator](#): Tool to estimate supported maximum current and ripple for specified conditions.

**Top-Level Interconnect Simplified Diagram**

Figure 2 shows the same major blocks as the *Typical Applications Circuit* with an increased emphasis on the routing between each block. This diagram is intended to familiarize the user with the landscape of the device. Many of the details associated with these signals are discussed throughout the data sheet. At this stage of the data sheet, note the addition of the main bias and clock block that are not shown in the *Typical Applications Circuit* section. The main bias and clock block provides voltage, current, and clock references for other blocks as well as many resources for the top-level digital control.

Figure 2. Top-Level Interconnect Simplified Diagram

## Detailed Description—Global Resources

The global resources encompass a set of circuits that serve the entire device and ensure safe, consistent, and reliable operation.

### Features and Benefits

- Voltage Monitors
  - AVL POR (power-on-reset) comparator generates a reset signal upon power-up.
  - AVL undervoltage ensures repeatable behavior when power is applied to and removed from the device.
  - SYS overvoltage monitor inhibits operation with overvoltage power sources to ensure reliability in faulty environments.
- Thermal Monitors
  - +165°C junction temperature shutdown
- Manual Reset
  - 3.3s or 8s period
- Wake-Up Events
  - Charger insertion (with 120ms debounce)
  - nEN input assertion
- Interrupt Handler
  - Interrupt output (nIRQ)
  - All interrupts are maskable
- Push-Button/Slide-Switch On-key (nEN)
  - Configurable push-button/slide-switch functionality
  - 500 $\mu$ s or 30ms debounce timer interfaces directly with mechanical switches
- On/Off Controller
  - Startup/shut-down sequencing
  - Programmable sequencing delay
- GPIO, RST Digital I/Os

### Voltage Monitors

The device monitors the AVL voltage to ensure proper operation using three comparators (POR, UVLO, and OVLO). These comparators include hysteresis to prevent their outputs from toggling between states during noisy system transitions.

#### AVL POR Comparator

The AVL POR comparator monitors  $V_{AVL}$  and generates a power-on reset signal (POR). When  $V_{AVL}$  is below  $V_{POR}$ , the device is held in reset (AVLRST = 1). When  $V_{AVL}$  rises above  $V_{POR}$ , internal signals and on-chip memory stabilize and the device is released from reset (AVLRST = 0).

#### AVL Undervoltage-Lockout Comparator

The AVL undervoltage-lockout (UVLO) comparator monitors  $V_{AVL}$  and generates an AVLUVLO signal when the  $V_{AVL}$  falls below UVLO threshold. The AVLUVLO signal is provided to the top-level digital controller. See [Figure 6](#) and [Table 4](#) for additional information regarding the UVLO comparator:

- When the device is in the standby state, the UVLO comparator is disabled.
- When transitioning out of the standby state, the UVLO comparator is enabled allowing the device to check for sufficient input voltage. If the device has sufficient input voltage, it can transition to the resource-on state; if there is insufficient input voltage, the device transitions back to the standby state.

### SYS Overvoltage-Lockout Comparator

The device is rated for 5.5V maximum operating voltage ( $V_{SYS}$ ) with an absolute maximum input voltage of 6.0V. An overvoltage-lockout monitor increases the robustness of the device by inhibiting operation when the supply voltage is greater than  $V_{SYSOVLO}$ . See [Figure 6](#) and [Table 4](#) for additional information regarding the OVLO comparator:

- When the device is in the standby state, the OVLO comparator is disabled.

### Chip Identification

The MAX77659 offers different one-time-programmable (OTP) options to, for example, set the default output voltages. These options are identified by the chip identification number, which can be read in the CID register.

### nEN Enable Input

nEN is an active-low internally debounced digital input that typically comes from the system's on-key. The debounce time is programmable with  $CNFG\_GLBL.DBEN\_nEN$ . The primary purpose of this input is to generate a wake-up signal for the PMIC that turns on the regulators. Maskable rising/falling interrupts are available for nEN ( $INT\_GLBL0.nEN\_R$  and  $INT\_GLBL0.nEN\_F$ ) for alternate functionality.

The nEN input can be configured to work either with a push-button ( $CNFG\_GLBL.nEN\_MODE = 0$ ) or a slide-switch ( $CNFG\_GLBL.nEN\_MODE = 1$ ). See [Figure 3](#) for more information. In both push-button mode and slide-switch mode, the on/off controller looks for a falling edge on the nEN input to initiate a power-up sequence.

### nEN Manual Reset

nEN works as a manual reset input when the on/off controller is in the resource-on state. The manual reset function is useful for forcing a power-down in case communication with the processor fails. When nEN is configured for push-button mode and the input is asserted ( $nEN = LOW$ ) for an extended period ( $t_{MRST}$ ), the on/off controller initiates a power-down sequence and goes to standby mode. When nEN is configured for slide-switch mode and the input is deasserted ( $nEN = HIGH$ ) for an extended period ( $t_{MRST}$ ), the on/off controller initiates a power-down sequence and goes to standby mode.

### nEN Dual-Functionality: Push-Button vs. Slide-Switch

The nEN digital input can be configured to work with a push-button or a slide-switch. The following timing diagram shows nENs dual functionality for power-on sequencing and manual reset. The default configuration of the device can be either push-button mode ( $CNFG\_GLBL.nEN\_MODE = 0$ ) or slide-switch mode  $CNFG\_GLBL.nEN\_MODE = 1$  with OTP options.

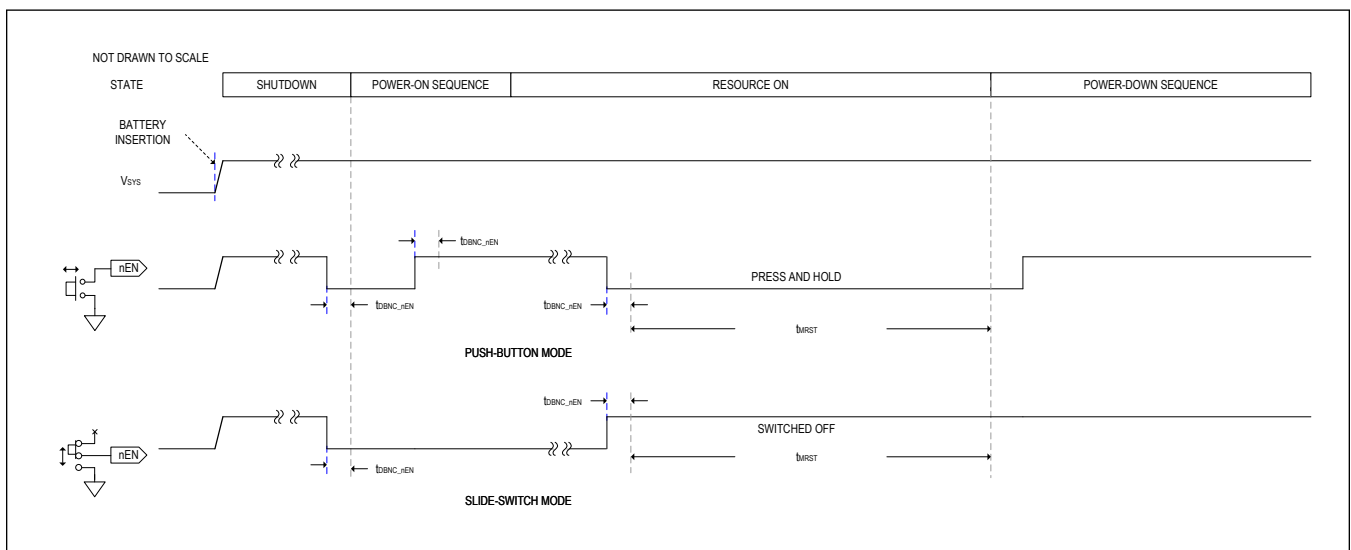

Figure 3. nEN Usage Timing Diagram

### nEN Internal Pullup Resistors to V<sub>CCINT</sub>

The nEN logic thresholds are referenced to V<sub>CCINT</sub>, an always-on internal voltage domain. There are internal pullup resistors between nEN and V<sub>CCINT</sub> (R<sub>nEN\_PU</sub>), which can be configured with the CNFG\_GLBL\_A.PU\_DIS bit. See [Figure 4](#). While PU\_DIS = 0, the pullup value is approximately 200kΩ. While PU\_DIS = 1, the pullup value is 10MΩ.

V<sub>CCINT</sub> is defined by the following conditions:

- V<sub>CCINT</sub> = V<sub>CHGIN</sub> if CHGIN is valid (STAT\_CHG\_B.CHGIN\_DTLS[1:0] = 0b11) and not USB suspended (CNFG\_CHG\_G.USBS = 0).
- V<sub>CCINT</sub> = V<sub>BATT</sub> if CHGIN is invalid (STAT\_CHG\_B.CHGIN\_DTLS[1:0] ≠ 0b11) or CHGIN is valid but USB suspended (CNFG\_CHG\_G.USBS = 1).

Applications using a slide-switch on-key or push-pull digital output connected to nEN can reduce quiescent current consumption by changing pullup strength to 10MΩ. Applications using normally-open, momentary, and push-button on-keys (as shown in [Figure 4](#)) do not create this leakage path and should use the stronger 200kΩ pullup option.

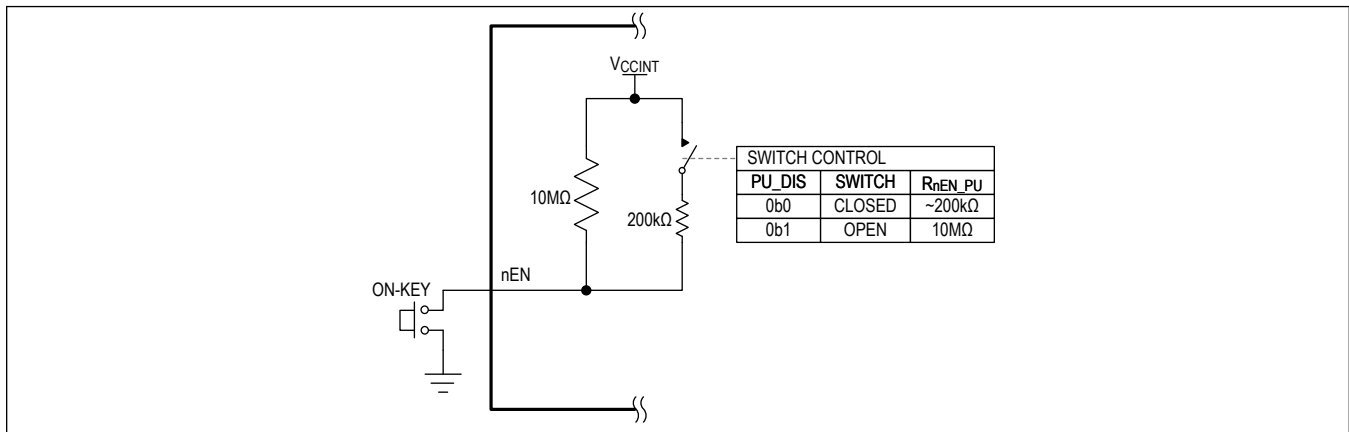

Figure 4. nEN Pullup Resistor Configuration

### Interrupts (nIRQ)

nIRQ is an active-low, open-drain output that is typically routed to the host processor's interrupt input to signal an important change in device status. See the [Register Map](#) section for a comprehensive list of all interrupt bits and status registers.

A pullup resistor to a voltage less than or equal to V<sub>SYS</sub> is required for this node. nIRQ is the logical *NOR* of all unmasked interrupt bits in the register map.

All interrupts are masked by default. Masked interrupt bits do not cause the nIRQ pin to change. Unmask the interrupt bits to allow nIRQ to assert.

### Reset Output (nRST)

nRST is an open-drain, active-low output that is typically used to hold the processor in a reset state when the device is powered down. During a power-up sequence, the nRST deasserts after the last regulator in the power-up chain is enabled (t<sub>RSTODD</sub>). During a power-down sequence, the nRST output asserts before any regulator is powered down (t<sub>RSTOAD</sub>). See [Figure 10](#) for nRST timing.

A pullup resistor to a voltage less than or equal to V<sub>SYS</sub> is required for this node.

### General-Purpose Input Output (GPIO)

The provided general-purpose input/output (GPIO) pins increase system flexibility. See [Figure 5](#) for more details.

Clear CNFG\_GPIOx.DIR to configure GPIO as a general-purpose output (GPO). The GPO can either be in push-pull mode (CNFG\_GPIOx.DRV = 1) or open-drain mode (CNFG\_GPIOx.DRV = 0).

- The push-pull output mode is ideal for applications that need fast (~2ns) edges and low power consumption.
- The open-drain mode requires an external pullup resistor (typically 10kΩ to 100kΩ). Connect the external pullup resistor to a bias voltage that is less than or equal to  $V_{IO}$ .
  - The open-drain mode can be used to communicate to different logic domains. For example, to send a signal from the GPO on a 1.8V logic domain ( $V_{IO} = 1.8V$ ) to a device on a 1.2V logic domain, connect the external pullup resistor to 1.2V.
  - The open-drain mode can be used to connect several open-drain (or open-collector) devices together on the same bus to create wired logic (wired AND logic is positive-true; wired OR logic is negative-true).
- The general-purpose input (GPI) functions are still available while the pin is configured as a GPO. In other words, the CNFG\_GPIOx.DI (input status) bit still functions and does not collide with the state of the CNFG\_GPIOx.DIR bit.

Set CNFG\_GPIOx.DIR to have the GPIO function as a GPI. The GPI features a 30ms debounce timer ( $t_{DBNC\_GPI}$ ) that can be enabled or disabled with DBEN\_GPI.

- Enable the debounce timer (CNFG\_GPIOx.DBEN\_GPI = 1) if the GPI is connected to a device that can bounce or chatter, like a mechanical switch.
- If the GPI is connected to a circuit with clean logic transitions and no risk of bounce, disable the debounce timer (CNFG\_GPIOx.DBEN\_GPI = 0) to eliminate logic delays. With no debounce timer, the GPI input logic propagates to nIRQ in 10ns.

A dedicated internal oscillator is used to create the 30ms ( $t_{DBNC\_GPI}$ ) debounce timer. To obtain low  $V_{IO}$  supply current, ensure the GPIO voltage is either logic high or logic low. If the GPIO pin is unconnected (either as a GPI or an open-drain GPO) and  $V_{IO}$  is powered, the GPIO voltage trends towards the logic level gray area ( $0.3 \times V_{IO} < V_{GPIO} < 0.7 \times V_{IO}$ ). If  $V_{GPIO}$  is in the gray area,  $V_{IO}$  current can be more than 10μA.

The GPI features edge detectors that feed into the the top-level interrupt system of the chip. This allows software to use interrupts to service events associated with a GPI change instead of polling for these changes.

- If the application wants nIRQ to go low **only on a GPI rising edge**, then it should **clear** the GPI rising edge interrupt mask bit (INTM\_GLBL1.GPI\_RM = 0) and **set** the GPI falling edge interrupt mask bit (INTM\_GLBL1.GPI\_FM = 1).
- If the application wants nIRQ to go low **only on a GPI falling edge**, then it should **set** the GPI rising edge interrupt mask bit (INTM\_GLBL1.GPI\_RM = 1) and **clear** the GPI falling edge interrupt mask bit (INTM\_GLBL1.GPI\_FM = 0).
- If the application wants nIRQ to go low **on both GPI falling and rising edges**, then it should **clear** the GPI rising edge interrupt mask bit (INTM\_GLBL1.GPI\_RM = 0) and **clear** the GPI falling edge interrupt mask bit (INTM\_GLBL1.GPI\_FM = 0).

Figure 5. GPIOx Block Diagram

**Alternate Mode**

Each GPIO in the MAX77659 can be configured to have a different function. Whether a particular GPIO is in GPIO mode or an alternate mode can be checked by reading the CNFG\_GPIOx.ALT\_GPIOx bit. Table 3 summarizes the alternate functions for each GPIO.

**Table 3. GPIO Mode**

GPIOx	CNFG_GPIOx REGISTER	
	ALT_GPIOx = 0	ALT_GPIOx = 1
GPIO0	Standard GPIO	Active-high input, enable control for low-power mode.
GPIO1	Standard GPIO	Active-high input, controls the DVS feature for SBB0.

The value of GPIO0 is OR'd with CNFG\_GLBL.SBIA\_LPM, so setting SBIA\_LPM = 1 or setting GPIO0 HIGH in alternate mode requests bias lower-power mode.

**On/Off Controller**

The on/off controller monitors multiple power-up (wake-up) and power-down (shutdown) conditions to enable or disable resources that are necessary for the system and its processor to move between its operating modes.

Many systems have one power management controller and one processor and rely on the on/off controller to be the master controller. In this case, the on/off controller receives wake-up events and enables some or all of the regulators to power-up a processor. That processor then manages the system. To conceptualize this master operation, see Figure 6 and Table 4. A typical path through the on/off controller is:

1. Apply a battery and start in the shutdown state.
2. Press the system's on-key (nEN = LOW) and follow transitions 4 and 6 to the resource-on state. If any resources are on the FPS, transitions 7A and 7B are followed.
3. The device performs its desired functions in the resource-on state. When it is ready to turn off, a manual reset first drives the transition through transitions 8A and 8B to the standby state. Afterward, the device automatically follows

transition 3 to the shutdown state.

Some systems have several power management blocks, a main processor, and subprocessors. These systems can use this device as a subpower management block for a peripheral portion of circuitry as long as there is an I<sup>2</sup>C port available from a higher level processor. To conceptualize this operation, see [Figure 6](#) and [Table 4](#). A typical path through the on/off controller used in this way is:

1. Apply a battery to the system and start in the shutdown state.
2. When the higher level processor wants to turn on this device's resources, it enables the main bias circuits through I<sup>2</sup>C (CNFG\_GLBL.SBIA\_EN = 1) to transition along path 6 to the resource-on state.
3. The higher level processor can now control this device's resources with I<sup>2</sup>C commands, e.g., turn on/off regulators.
4. When the higher level processor is ready to turn this device off, it turns off everything through I<sup>2</sup>C and then disables the main bias circuits through I<sup>2</sup>C (CNFG\_GLBL.SBIA\_EN = 0) to transition along path 5B to the standby state.

Note that in this style of operation, the CNFG\_GLBL\_SFT\_CTRL[1:0] bits should not be used to turn the device off. The CNFG\_GLBL\_SFT\_CTRL[1:0] bits establish directives to the on/off controller itself that does not make sense in this subpower management block operation. If the processor uses I<sup>2</sup>C commands to enable the device's resources, the processor should also use I<sup>2</sup>C commands to disable them.

**Top Level On/Off Controller**

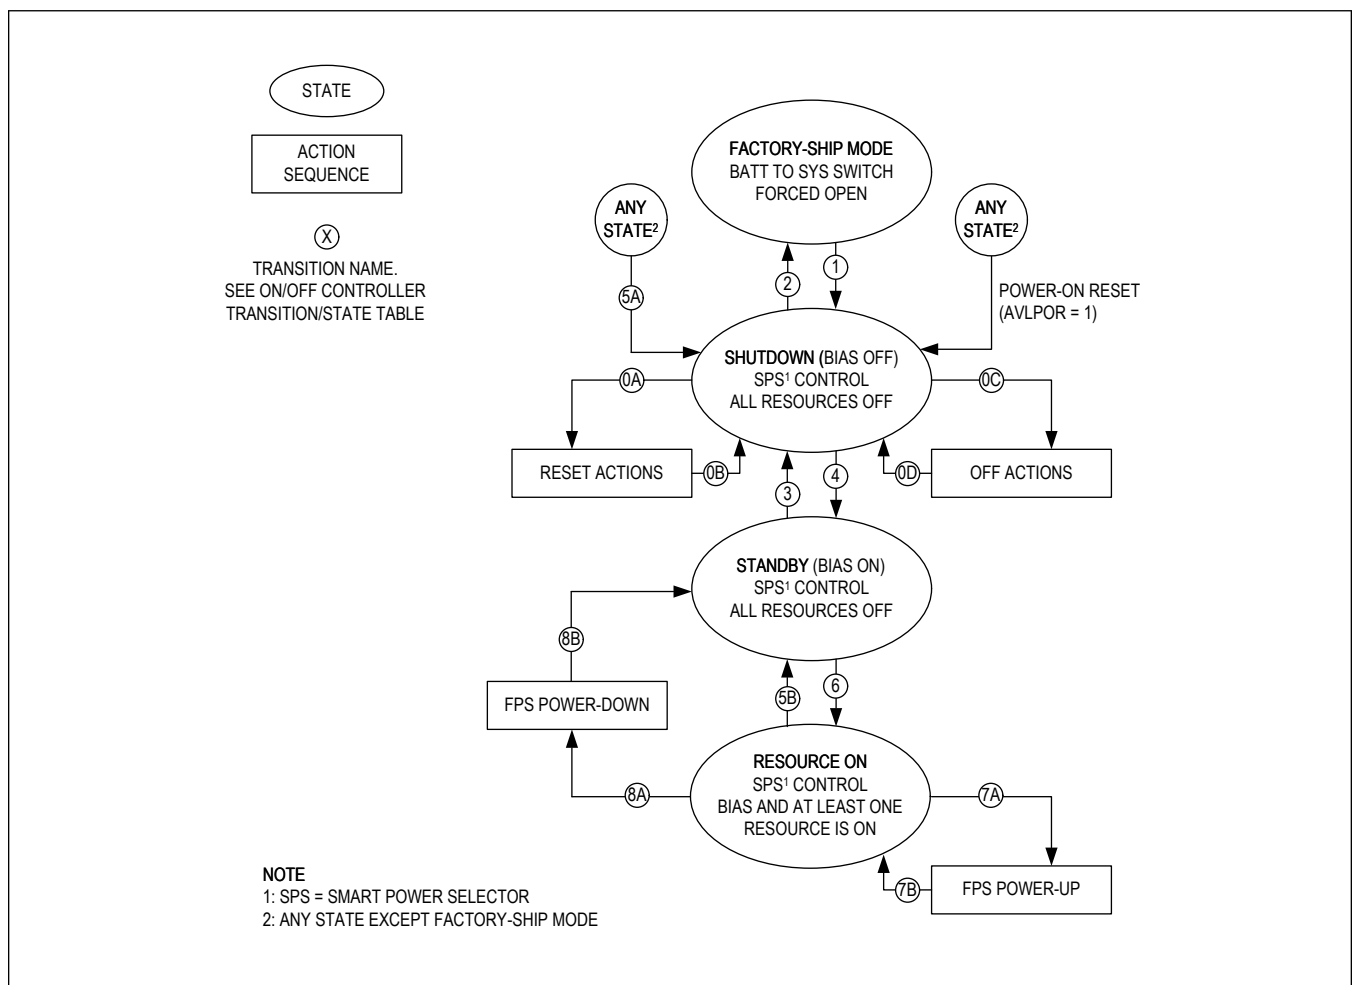

Figure 6. Top Level On/Off Controller State Diagram

## On/Off Controller Transition Table

Table 4. On/Off Controller Transition/State

TRANSITION	CONDITION (TRANSITION HAPPENS WHEN...)
0A	Software cold reset (CNFG_GLBL.SFT_CTRL[1:0] = 0b01) <b>OR</b> Watchdog timer expired and caused reset (ERCFLAG.WDT_RST = 1, CNFG_WDT.WDT_MODE = 1)
0B	Reset actions completed
0C	Software power-off (CNFG_GLBL.SFT_CTRL[1:0] = 0b10) <b>OR</b> Watchdog expired and caused power-off (ERCFLAG.WDT_OFF = 1, CNFG_WDT.WDT_MODE = 0) <b>OR</b> Chip over-temperature lockout ( $T_J > T_{OTLO}$ ) <b>OR</b> SYS undervoltage lockout ( $V_{SYS} < V_{SYSUVLO} + V_{SYSUVLO\_HYS}$ ) <b>OR</b> SYS overvoltage lockout ( $V_{SYS} > V_{SYSOVLO}$ ) <b>OR</b> Manual reset occurred (ERCFLAG.MRST = 1)
0D	Off actions completed
1	CHGIN inserted and 120ms debounce valid (STAT_CHG_B.CHGIN_DTLS[1:0] = 0b11) <b>OR</b> nEN asserted and debounced ( $t_{FSM-DB}$ ) <b>OR</b> Power to the IC is removed ( $V_{BATT} < \text{approx. } 1.6V$ ) and then reapplied ( $V_{BATT} > V_{POR}$ )
2	Factory-ship mode requested (CNFG_GLBL.SFT_CTRL[1:0] = 0b11) <b>AND</b> nEN not asserted
3	<b>NOT</b> (Transition 4) Factory-ship mode requested (CNFG_GLBL.SFT_CTRL[1:0] = 0b11) <b>OR</b> Software cold reset (CNFG_GLBL.SFT_CTRL[1:0] = 0b01) <b>OR</b> Software power-off (CNFG_GLBL.SFT_CTRL[1:0] = 0b10) <b>OR</b> Watchdog timer expired <b>OR</b> Manual reset occurred (ERCFLAG.MRT = 1)
4	Main bias request enabled through I <sup>2</sup> C (CNFG_GLBL.SBIA_EN = 1) <b>OR</b> Transition 6
5A	Chip over-temperature lockout ( $T_J > T_{OTLO}$ ) <b>OR</b> SYS undervoltage lockout ( $V_{SYS} < V_{SYSUVLO} + V_{SYSUVLO\_HYS}$ ) <b>OR</b> SYS overvoltage lockout ( $V_{SYS} > V_{SYSOVLO}$ )
5B	<b>NOT</b> (Transition 6) <b>OR</b> Factory-ship mode requested (CNFG_GLBL.SFT_CTRL[1:0] = 0b11) <b>OR</b> Software cold reset (CNFG_GLBL.SFT_CTRL[1:0] = 0b01) <b>OR</b> Software power-off (CNFG_GLBL.SFT_CTRL[1:0] = 0b10) <b>OR</b> Watchdog timer expired <b>OR</b> Manual reset occurred (ERCFLAG.MRT = 1)
6	AMUX is being used (CNFG_CHG_I.MUX_SEL[3:0] $\neq$ 0b0000) <b>OR</b> CHGIN inserted and debounced (STAT_CHG_B.CHGIN_DTLS[1:0] = 0b11) <b>OR</b> Any resources force enabled <b>OR</b> Internal wake-up flags are set (see the <a href="#">Internal Wake-Up Flags</a> section)
7A	FPS power-up sequence has not happened yet <b>AND</b> Resources are not forced off <b>AND</b> Internal wake-up flags are set (see the <a href="#">Internal Wake-Up Flags</a> section)
7B	FPS power-up sequence done
8A	FPS power-up sequence completed <b>AND</b> All resources are force disabled <b>OR</b> Factory-ship mode requested (CNFG_GLBL.SFT_CTRL[1:0] = 0b11) <b>OR</b> Software cold reset (CNFG_GLBL.SFT_CTRL[1:0] = 0b01) <b>OR</b> Software power-off (CNFG_GLBL.SFT_CTRL[1:0] = 0b10) <b>OR</b> Watchdog timer expired <b>OR</b> Manual reset occurred (ERCFLAG.MRT = 1)
8B	FPS power-down sequence finished

**Internal Wake-Up Flags**

After transitioning to the shutdown state because of a reset, to allow the device to power-up again, internal wake-up flags are set to remember the wake-up request. In [Figure 6](#) and [Table 4](#), these internal wake-up flags trigger transitions 6 and 7A. The internal wake-up flags are set when any of the following happen:

- nEN is debounced (see the [nEN Enable Input](#) section)
  - For example, after a push-button is pressed or a slide-switch switched to HIGH.
- CHGIN is debounced and valid (STAT\_CHG\_B.CHGIN\_DTLS[1:0] = 0b11)
- Software cold reset command sent (CNFG\_GLBL.SFT\_CTRL[1:0] = 0b01)

**Reset and Off Sequences**

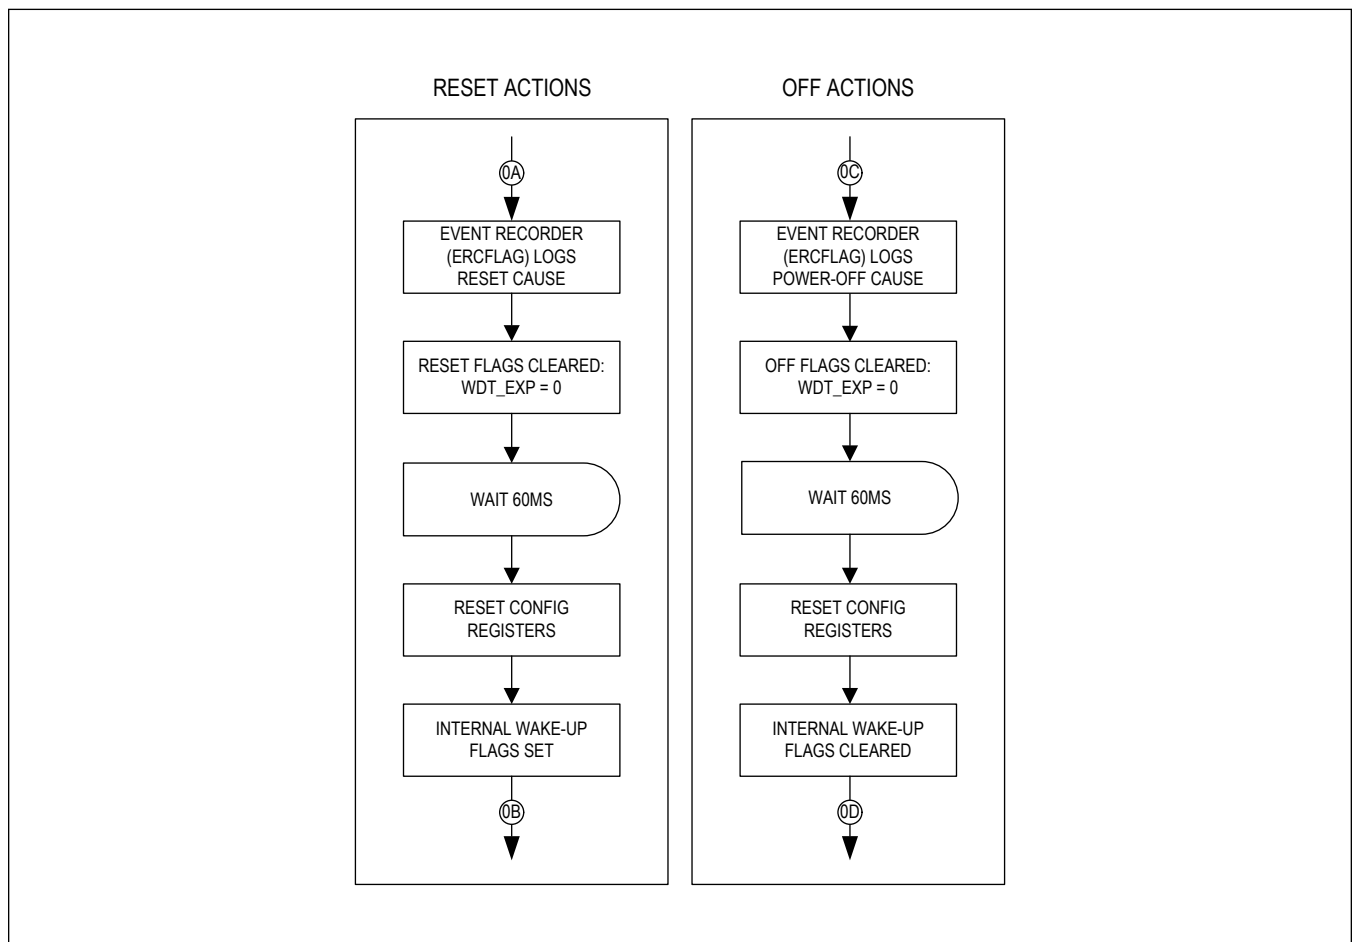

Figure 7. On/Off Controller Reset and Off-Action Sequences

Power-Up/Down Sequence

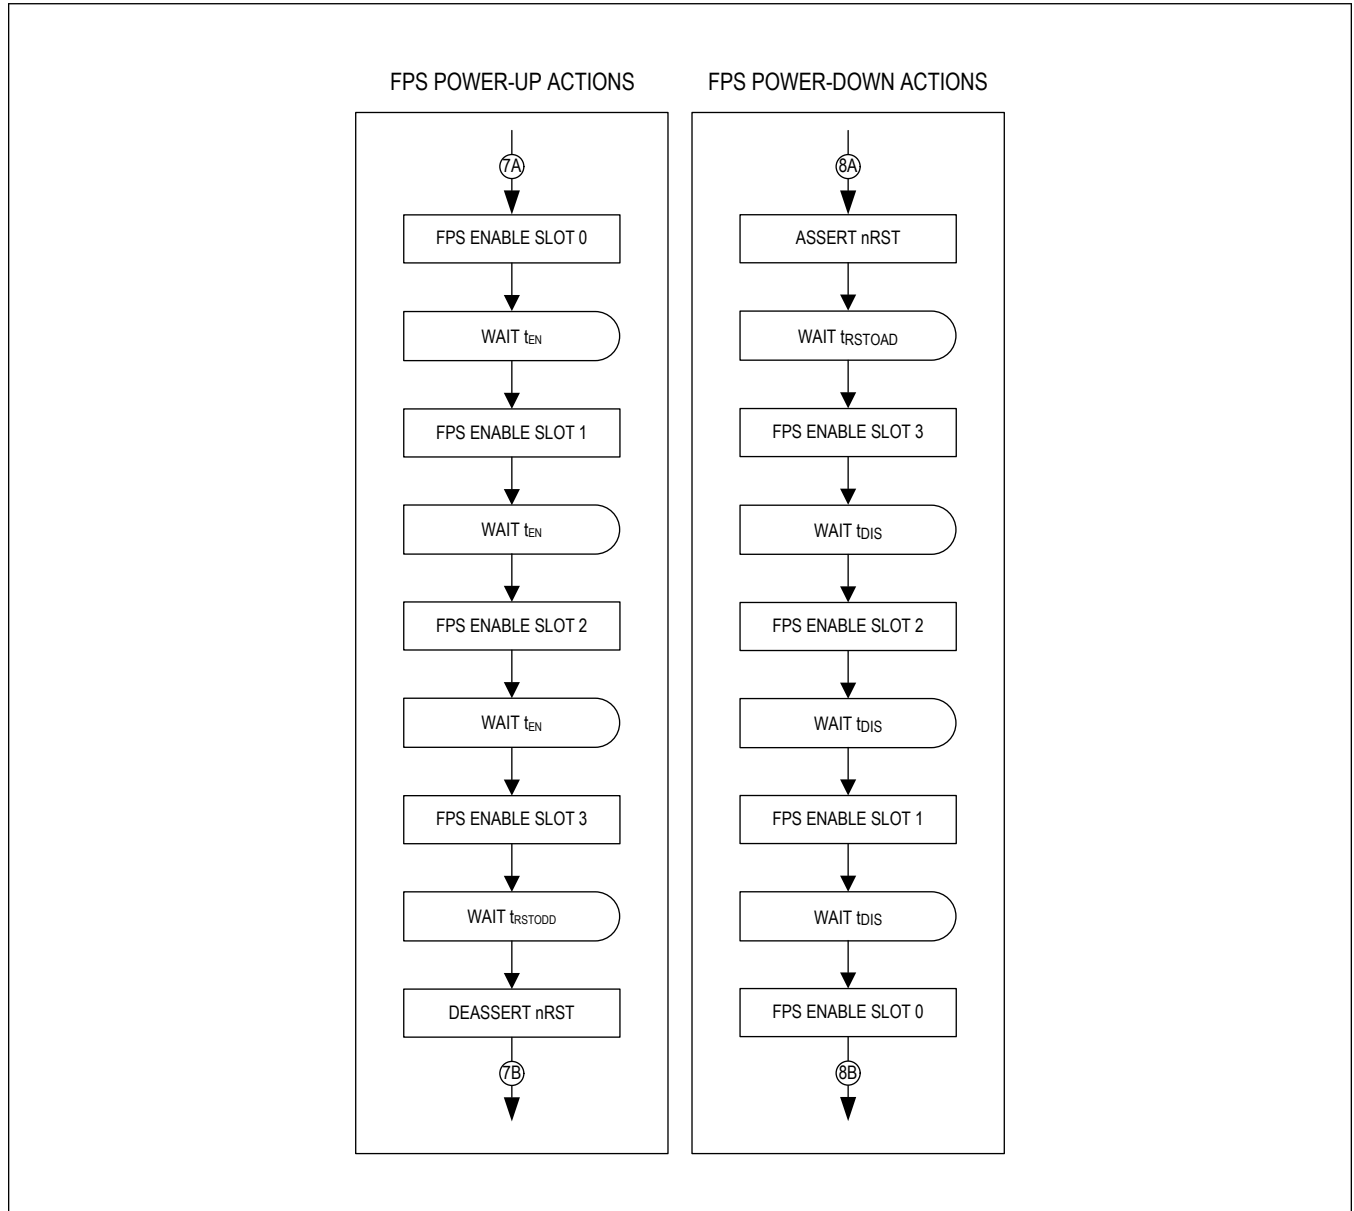

Figure 8. Power-Up/Down Sequence

**Flexible Power Sequencer (FPS)**

The FPS allows resources to power up under hardware or software control. Additionally, each resource can power up independently or among a group of other regulators with adjustable power-up/down delays (sequencing). [Figure 9](#) shows four resources powering up under the control of the flexible power sequencer.

The flexible sequencing structure consists of one master sequencing timer and four slave resources (SBB0, SBB1, SBB2 and LDO). When the FPS is enabled, a master timer generates four sequencing events for device power-up/down.

Figure 9. Flexible Power Sequencer Basic Timing Diagram

Startup Timing Diagram Due to nEN

Figure 10. Startup Timing Diagram Due to nEN

Startup Timing Diagram Due to Charge Source Insertion

Figure 11. Startup Timing Diagram Due to Charge Source Insertion

Force Enabled/Disabled Channels

Force enable SIMO and LDO output channels by setting CNFG\_SBBx\_B.EN\_SBBx[2:0] (SIMO) or CNFG\_LDOx\_B.EN\_LDOx[2:0] (LDO) = 0x6 or 0x7. Depending on the OTP, output channels may already be force enabled by default. Output channels configured this way are independent of the flexible power sequence and start up as soon as AVL > UVLO rising. The main bias also automatically turns on.

Likewise, output channels can be force disabled by setting EN\_SBBx[2:0] or EN\_LDOx[2:0] = 0x4 or 0x5.

### Factory-Ship Mode State

Factory-ship mode internally disconnects the battery (BATT) from the system (SYS). The battery does not power the system in this mode. Use this mode to preserve battery life if external circuits on SYS cause the battery to leak.

Write `CNFG_GLBL.SFT_CTRL[1:0] = 0b11` using I<sup>2</sup>C to enter factory-ship mode. The IC responds in two different ways depending on the state of the charger input (CHGIN):

- If CHGIN is valid (`STAT_CHG_B.CHGIN_DTLS[1:0] = 0b11`) while `CNFG_GLBL.SFT_CTRL[1:0] = 0b11`, then the IC enters factory-ship mode (internally disconnects BATT from SYS) but SYS is still powered from CHGIN (regulating to  $V_{SYS-REG}$ ). SYS decays to 0V when CHGIN is disconnected.
- If CHGIN is invalid (`STAT_CHG_B.CHG_DTLS[1:0] ≠ 0b11`) while `CNFG_GLBL.SFT_CTRL[1:0] = 0b11`, then the IC enters factory-ship mode and SYS decays to 0V.

Factory-ship mode causes many configuration registers to reset (AVLRST). See the [Register Map](#) section for details. I<sup>2</sup>C reads and writes cannot happen in factory-ship mode.

Factory-ship mode exits only after SYS decays below approximately 1.8V. Once this condition is met, there are two ways to exit factory-ship mode:

- Apply a valid DC source at CHGIN for  $t_{CHGIN-DB}$  (120ms, typ). Factory-ship mode is unlatched (exited) when the charger input becomes valid from a previously invalid state (`STAT_CHG_B.CHGIN_DTLS[1:0] = 0b00 → 0b11`).
- Assert nEN for  $t_{FSM-EXDB}$  (250ms typical) +  $t_{DBNC\_nEN}$ .

Furthermore, this state is unlatched if power is removed from the IC (BATT voltage falls below approximately 1.8V). In all exit cases, the smart power selector controls the interaction between BATT and SYS until factory-ship mode is entered again (see the [Smart Power Selector](#) section).

### Debounced Inputs (nEN, GPI, CHGIN)

nEN, CHGIN, and GPIO (when operating as an input, and `GNFG_GPIOx.DBEN_GPI = 1`), are debounced on both rising and falling edges to reject undesired transitions. The input must be at a stable logic level for the entire debounce period for the output to change its logic state. [Figure 12](#) shows an example timing diagram for the nEN debounce.

Figure 12. Debounced Inputs

### Watchdog Timer (WDT)

The IC features a watchdog timer function for operational safety. If this timer expires without being cleared, the on/off controller causes the IC to enter the shutdown state and resets configuration registers. See the [On/Off Controller](#) and [On/Off Controller Transition Table](#) sections (transitions 0A and 0C) for more details.

Write `CNFG_WDT.WDT_EN = 1` through I<sup>2</sup>C to enable the timer. The watchdog timer period ( $t_{WD}$ ) is configurable from 16 to 128 seconds in four steps with `CNFG_WDT.WDT_PER[1:0]`. The default timer period is 128 seconds. While the watchdog timer is enabled, the `CNFG_WDT.WDT_CLR` bit must be set through I<sup>2</sup>C periodically (within  $t_{WD}$ ) to reset the timer and prevent shutdown. See the [Register Map](#) and [Figure 13](#) for additional details.

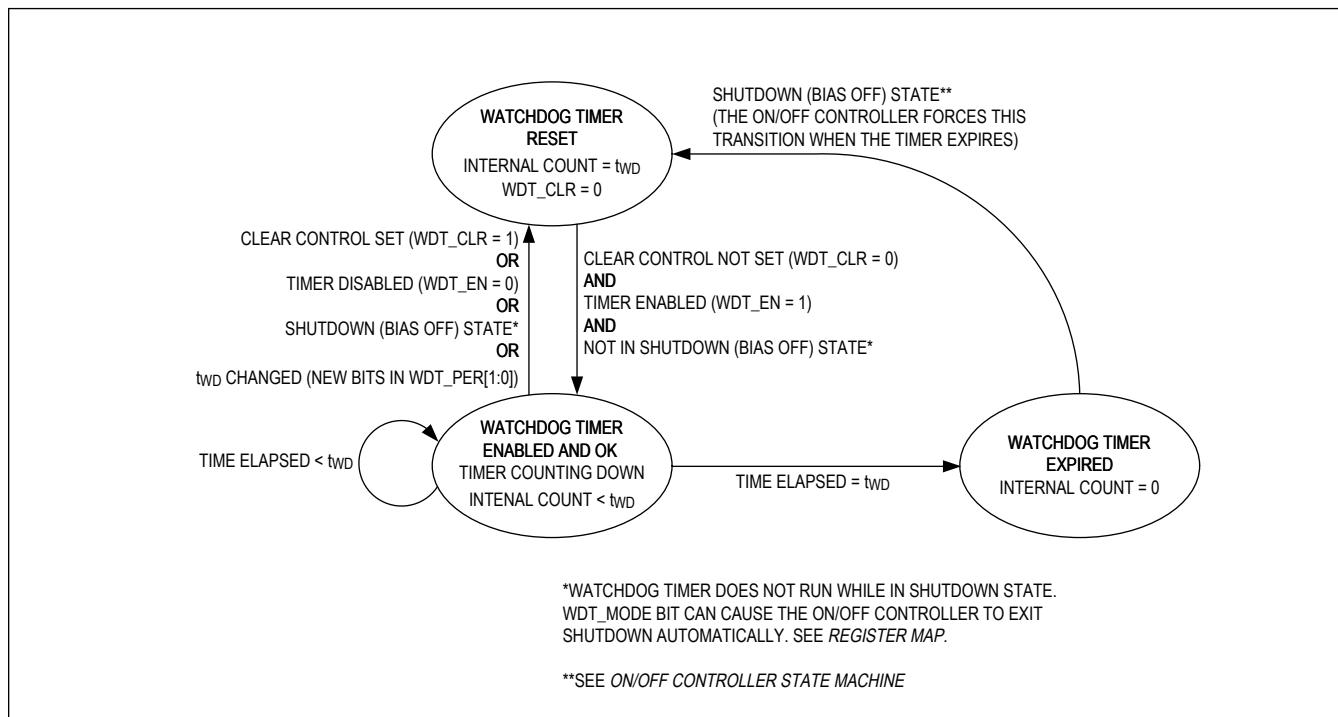

Figure 13. Watchdog Timer State Machine

The timer can be factory-programmed to be enabled by default, disabled by default, or locked from accidental disable. The `CNFG_WDT.WDT_LOCK` bit is read-only and must be configured at the factory. See [Table 5](#) for a full description.

**Table 5. Watchdog Timer Factory-Programmed Safety Options**

WDT_LOCK	WDT_EN	FUNCTION
0	0	Watchdog timer is disabled by default. Timer can be enabled or disabled by I <sup>2</sup> C writes.
0	1	Watchdog timer is enabled by default. Timer can be enabled or disabled by I <sup>2</sup> C writes.
1	0	Watchdog timer is disabled by default. Timer can be enabled by an I <sup>2</sup> C write, but only a AVLRST can reset the <code>CNFG_WDT.WDT_EN</code> value back to 0. Timer can not be disabled by direct I <sup>2</sup> C writes to <code>CNFG_WDT.WDT_EN</code> (write from 1 → 0 is ignored, write from 0 → 1 is accepted).
1	1	Watchdog timer is enabled by default. Nothing can disable the timer.

## Detailed Description—SIMO Buck-Boost

The device has a micropower single-inductor, multiple-output (SIMO) buck-boost DC-to-DC converter designed for applications that emphasize low supply current and small solution size. A single inductor is used to regulate three separate power outputs and one charging output, saving board space while delivering better total system efficiency than equivalent power solutions using one linear charger, one buck, and linear regulators.

The charging output of this 4-rail SIMO regulator is used to provide headroom control to reduce heat dissipation and improve overall system efficiency during the charging process. See the [Smart Power Selector Charger](#) section for more details.

For the three power outputs, the buck-boost configuration utilizes the entire battery voltage range due to its ability to create output voltages that are above, below, or equal to the input voltage. Peak inductor current for each output is programmable to optimize the balance between efficiency, output ripple, EMI, PCB design, and load capability.

To further boost efficiency when the output voltage is always lower than the input, individual channels of the SIMO buck-boost converter can be configured to be in buck mode, reducing switching losses by toggling fewer switches compared to buck-boost mode. See the [SIMO Buck Mode](#) section for more details.

### SIMO Features and Benefits

- Three Power Output Channels
- One Charging Output Channel
- Ideal for Low-Power Designs
  - Delivers 500mA at 1.8V Output in Buck Mode and 3.7V Input
- Small Solution Size
  - Multiple Outputs from a Single Inductor
- Flexible and Easy to Use
  - Buck and Buck-Boost Modes of Operation
  - Glitchless Transitions Between Buck and Buck-Boost Modes
  - Programmable Peak Inductor Current
  - Programmable On-Chip Active Discharge
- Long Battery Life
  - High Efficiency, > 90% at 1.8V Output in Buck Mode and 3.7V Input
  - Higher Total System Efficiency than Buck + LDOs Solution
  - Low Quiescent Current, 1µA per Output
  - Low Input Operating Voltage, 2.7V (min)

**SIMO Detailed Block Diagram**

Figure 14. SIMO Detailed Block Diagram (when CHGIN = 0V)

**SIMO Control Scheme**

The SIMO buck-boost is designed to service multiple outputs simultaneously. A proprietary controller ensures that all outputs get serviced in a timely manner, even while multiple outputs are contending for the energy stored in the inductor. When no regulator needs service, the state machine rests in a low-power rest state.

When the controller determines that a regulator requires service, it charges the inductor (M1 + M4) until the peak current limit is reached ( $I_{LIM} = CNFG\_SBBx\_B.IP\_SBB[1:0]$ ). The inductor energy then discharges (M2 + M3\_x) into the output until the current reaches zero ( $I_{ZX}$ ). In the event that multiple output channels need servicing at the same time, the controller ensures that no output utilizes all of the switching cycles. Instead, cycles interleave between all the outputs that are demanding service, while outputs that do not need service are skipped.

### Drive Strength

The SIMO regulator's drive strength for its internal power MOSFETs is adjustable using the CNFG\_SBB\_TOP.DRV\_SBB[1:0] bitfield. The ideal value is determined experimentally for each application. For a PCB layout comparable to the MAX77659 EV kit, 0x0 is the best setting. Faster settings result in higher efficiency but generally require stricter layout rules or shielding to avoid additional EMI. Slower settings limit EMI in non-ideal settings (e.g., contained layout, antennae adjacent to the device, etc.). Change the drive strength only once during system initialization.

### SIMO Soft-Start

The soft-start feature of the SIMO limits inrush current during startup. The soft-start feature is achieved by limiting the slew rate of the output voltage during startup ( $dV/dt_{SS}$ ).

More output capacitance results in higher input current surges during startup. The following set of equations and example describes the input current surge phenomenon during startup.

In buck-boost mode, the current into the output capacitor ( $I_{CSBB}$ ) during soft-start is:

$$I_{CSBB} = C_{SBB} \frac{dV}{dt_{SS}} \quad \left( \text{Equation 1} \right)$$

where:

- $C_{SBB}$  is the capacitance on the output of the regulator
- $dV/dt_{SS}$  is the voltage change rate of the output

The input current ( $I_{IN}$ ) during soft-start is:

$$I_{IN} = \frac{(I_{CSBB} + I_{LOAD}) \frac{V_{SBBx}}{V_{IN}}}{\xi} \quad \left( \text{Equation 2} \right)$$

where:

- $I_{CSBB}$  is from the calculation above
- $I_{LOAD}$  is current consumed from the external load
- $V_{SBBx}$  is the output voltage
- $V_{IN}$  is the input voltage
- $\xi$  is the efficiency of the regulator

For example, given the following conditions, the peak input current ( $I_{IN}$ ) during soft-start is ~71mA:

Given:

- $V_{IN}$  is 3.5V
- $V_{SBB2}$  is 3.3V
- $C_{SBB2} = 10\mu\text{F}$
- $dV/dt_{SS} = 5\text{mV}/\mu\text{s}$
- $R_{LOAD2} = 330\Omega$  ( $I_{LOAD2} = 3.3\text{V}/330\Omega = 10\text{mA}$ )
- $\xi$  is 80%

Calculation:

- $I_{CSBB} = 10\mu\text{F} \times 5\text{mV}/\mu\text{s}$  (from Equation 1)
- $I_{CSBB} = 50\text{mA}$
- $I_{IN} = \frac{(50\text{mA} + 10\text{mA}) \frac{3.3\text{V}}{3.5\text{V}}}{0.85}$  (from Equation 1)
- $I_{IN} \sim 71\text{mA}$

## SIMO Registers

Each SIMO buck-boost channel has a dedicated register to program its target output voltage (CNFG\_SBBx\_A.TV\_SBBx[6:0]) and its peak current limit (CNFG\_SBB\_TOP\_B.IP\_SBBx[1:0]). Additional controls are available for enabling/disabling the active-discharge resistors (CNFG\_SBBx\_B.ADE\_SBBx), buck mode (CNFG\_SBBx\_B.OP\_MODE), as well as enabling/disabling the SIMO buck-boost channels (CNFG\_SBBx\_B.EN\_SBBx[2:0]). For a full description of bits, registers, default values, and reset conditions, see the [Register Map](#) for more details.

## SIMO Active Discharge Resistance

Each SIMO buck-boost channel has an active-discharge resistor ( $R_{AD\_SBBx}$ ) that is automatically enabled/disabled based on a CNFG\_SBBx\_B.ADE\_SBBx bit and the status of the SIMO regulator. The active discharge feature may be enabled (CNFG\_SBBx\_B.ADE\_SBBx = 1) or disabled (CNFG\_SBBx\_B.ADE\_SBBx = 0) independently for each SIMO channel. Enabling the active discharge feature helps ensure a complete and timely power down of all system peripherals. If the active-discharge resistor is enabled by default, then the active-discharge resistor is on whenever  $V_{SYS}$  is below  $V_{SYSUVLO}$  and above  $V_{POR}$ .

These resistors discharge the output when CNFG\_SBBx\_B.ADE\_SBBx = 1, and their respective SIMO channel is off. If the regulator is forced on through CNFG\_SBBx\_B.EN\_SBBx[2:0] = 0b110 or 0b111, then the resistors do not discharge the output even if the regulator is disabled by the main-bias.

Note that when  $V_{SYS}$  is less than 1.0V, the NMOS transistors that control the active-discharge resistors lose their gate drive and become open.

## SIMO Buck Mode

If the input voltage at IN\_SBB never falls below the output voltage of one or more SIMO converter channels, individual channels can be configured to be in buck mode with the CNFG\_SBBx\_B.OP\_MODE bit. In buck mode, when an output needs service, switch M3\_x remains closed and M4 remains open (see [Figure 14](#)). Only M1 and M2 are toggled as in a traditional buck converter. Efficiency is boosted due to three major factors:

- Reduced switching loss: Buck mode toggles only two switches versus the four in buck-boost mode. Therefore, there are less switching events during which power is consumed.
- Lower inductor core losses: Inductor current changes from 0A to peak current. The larger the change in current the inductor experiences, the more energy is lost in the inductor core in the form of heat. In buck mode, the peak current can be reduced since less inductor current is needed to support a load. Less inductor current is needed because of direct energy transfer. Direct energy transfer occurs while the inductor is charged when the input (IN\_SBB) is connected directly to the output (SBBx) through the inductor. The input not only provides energy to charge the inductor but energy is also supplied to the output capacitor and load devices. Therefore, less current is needed to charge the inductor, which is used to charge the output capacitor in the next switching state.
- Less frequent charging cycles: In buck mode, the inductor is constantly connected to the serviced output during a switching cycle. In comparison, in buck-boost mode, the inductor is connected to the serviced output only when the inductor discharges. Thus, with the same peak inductor current limit, buck mode is capable of supplying higher load current than buck-boost mode. In addition, with the same load current and peak current limit, the switching frequency can be reduced with buck mode.

Maintain a minimum headroom of 0.7V between IN\_SBB and SBBx in buck mode because inductor charge time ( $dt = L \times I_{P\_SBBx} / (V_{IN\_SBB} - V_{SBBx})$ ) increases as the difference between the IN\_SBB and SBBx voltages shrinks. As the inductor current takes longer to reach its peak, the output voltage can take too long to reach its target voltage, and the MAX77659 can trigger a fault flag.

## Applications Information

### SIMO Available Output Current

The available output current on a given SIMO channel is a function of the input voltage, output voltage, the peak current limit setting, and the output current of the other SIMO channels. Maxim offers a calculator (see the [Support Material](#) section) that outlines the available capacity for specific conditions. [Table 6](#) is an extraction from the calculator.

**Table 6. SIMO Available Output Current for Common Applications**

PARAMETERS	EXAMPLE 1	EXAMPLE 2	EXAMPLE 3	EXAMPLE 4
V <sub>IN_SBB</sub>	3.7V	3.7V	3.2V	3.4V
R <sub>L_DCR</sub>	0.09Ω	0.09Ω	0.1Ω	0.12Ω
SBB0	1.0V at 100mA	1.0V at 80mA	1.2V at 50mA	1.2V at 20mA
SBB1	1.2V at 75mA	1.2V at 50mA	1.8V at 100mA	1.8V at 80mA
SBB2	1.8V at 50mA	1.8V at 40mA	3.3V at 30mA	3.3V at 10mA
Operating Mode	Buck	Buck	Buck/Buck-Boost	Buck/Buck-Boost
I <sub>P_SBB0</sub>	0.5A	0.5A	0.5A	0.5A
I <sub>P_SBB1</sub>	0.75A	0.5A	0.5A	0.5A
I <sub>P_SBB2</sub>	0.5A	0.5A	0.75A	0.5A
Utilized Capacity	81%	69%	78%	49%

\* $ESR_{C\_IN} = ESR_{C\_OUT} = 5m\Omega$ ,  $L = 1.5\mu H$

### Inductor Selection

Choose an inductance from 1.0μH to 2.2μH; 1.5μH inductors work best for most designs. Larger inductances transfer more energy to the output for each cycle and typically result in larger output voltage ripple and better efficiency. See the [Output Capacitor Selection](#) section for more information on how to size your output capacitor to control ripple.

Choose the inductor saturation current to be greater than or equal to the maximum peak current limit setting that is used for all of the SIMO buck-boost channels (I<sub>P\_SBBx</sub>). For example, if SBB0 is set for 0.5A, SBB1 is set for 0.75A, and SBB2 is set for 1.0A, then choose the saturation current to be greater than or equal to 1.0A.

Choose the RMS current rating of the inductor (typically the current at which the temperature rises appreciably) based on the expected load currents for the system. For systems where the expected load currents are not well known, be conservative and choose the RMS current to be greater than or equal to half the higher maximum peak current limit setting [ $I_{RMS} \geq \text{MAX}(I_{P\_SBB0}, I_{P\_SBB1}, I_{P\_SBB2})/\sqrt{3}$ ]. This is a conservative choice because the SIMO buck-boost regulator implements a discontinuous conduction mode (DCM) control scheme, which returns the inductor current to zero each cycle.

Consider the DC-resistance (DCR), AC-resistance (ACR), and solution size of the inductor. Typically, smaller-sized inductors have larger DC-resistance and larger AC-resistance that reduces efficiency and the available output current. Note that many inductor manufacturers have inductor families which contain different versions of core material to balance trade-offs between DCR, ACR (i.e., core losses), and component cost. For this SIMO regulator, inductors with the lowest ACR in the 1.0MHz to 2.0MHz region tend to provide the best efficiency.

### Input Capacitor Selection

Choose the input bypass capacitance ( $C_{IN\_SBB}$ ) to be 22 $\mu$ F. Larger values of  $C_{IN\_SBB}$  improve the decoupling for the SIMO regulator.

$C_{IN\_SBB}$  reduces the current peaks drawn from the battery or input power source during SIMO regulator operation and reduces switching noise in the system. The ESR/ESL of the input capacitor should be very low (i.e.,  $ESR \leq 5m\Omega$  and  $ESL \leq 500pH$ ) for frequencies up to 2MHz. Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients.

To fully utilize the available input voltage range of the SIMO (5.5V, max), use a capacitor with a voltage rating of 6.3V at minimum.

### Boost Capacitor Selection

Choose the boost capacitance ( $C_{BST}$ ) to be 10nF. Smaller values of  $C_{BST}$  result in insufficient gate drive for M3. Larger values of  $C_{BST}$  (> 10nF) have the potential to degrade the startup performance. Ceramic capacitors with 0201 or 0402 case sizes are recommended.

### Output Capacitor Selection

Choose each output bypass capacitance ( $C_{SBBx}$ ) based on the target output voltage ripple ( $\Delta V_{SBBx}$ ): typical values are 22 $\mu$ F. Larger values of  $C_{SBBx}$  improve the output voltage ripple but increase the input surge currents during soft-start and output voltage changes. The output voltage ripple is a function of the inductance (L), the output voltage ( $V_{SBBx}$ ), and the peak current limit setting ( $I_{P\_SBBx}$ ). See Equation 3 to estimate required, effective capacitance.

$$C_{SBBx} = \frac{I_{P\_SBBx}^2 \times L}{2 \times V_{SBBx} \times \Delta V_{SBBx}} \text{(Equation 3)}$$

Maxim also offers a calculator (see the [Support Materials](#) section) to aid in the selection of the output capacitance. Note that most designs concern themselves with having enough capacitance on the output but there is also a maximum capacitance limitation that is calculated within the SIMO calculator; take care not to exceed the maximum capacitance.

$C_{SBBx}$  is required to keep the output voltage ripple small. The impedance of the output capacitor (ESR, ESL) should be very low (i.e.,  $ESR \leq 5m\Omega$  and  $ESL \leq 500pH$ ) for frequencies up to 2MHz. Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients.

A capacitor's effective capacitance decreases with increased DC bias voltage. This effect is more pronounced as capacitor case sizes decrease. Due to this characteristic, in some use cases, an 0603 package size capacitor can perform well, while an 0402 package size capacitor of the same value performs poorly. The SIMO regulator is stable with low output capacitance (1 $\mu$ F) but the output voltage ripple would be large; consider the effective output capacitance value after initial tolerance, bias voltage, aging, and temperature derating.

### Example Component Selection

Pick input/output capacitors and the inductor for the given requirements:

- $V_{IN\_SBB} = 3.7V$

**Table 7. Design Requirements**

	<b>SBB0</b>	<b>SBB1</b>	<b>SBB2</b>
Output Voltage	3.3V	1.8V	1.2V
Maximum Load Current	50mA	45mA	80mA
Maximum Voltage Ripple	50mV	30mV	30mV

**Inductor, Peak Current Limit, and Input Capacitor**

For the best efficiency, a 1.5µH inductor is chosen. For this example, assume the DFE201610E-1R5M inductor from Murata is used. This particular inductor has 91mΩ of DCR.

Since the load current is low, first choose the inductor current peak to be 0.333A for all outputs. Next, enter these values into Maxim's SIMO calculator as mentioned previously.

Figure 15. Component Selection—High Utilization

As shown in Figure 15, the utilization is over 100%, which leads to output voltage droop. To lower utilization, increase the

inductor peak current limits. For this example, 0.75A is used for SBB0 and 0.5A for SBB1 and SBB2. Figure 16 shows the utilization of less than 80%. Using 0.5A for the inductor peak current limit has the added benefit of increased efficiency.

Figure 16. Component Selection—Final Current Peak Limits

To support the selected peak currents, choose 22μF for the input capacitor.

### Output Capacitors

Using Equation 3 and the selected inductor current peak limits, the minimum output capacitances required are:

$$C_{SBB0\_min} = \frac{I_{P\_SBB0}^2 \times L}{2 \times V_{SBB0} \times \Delta V_{SBB0}} = \frac{1^2 \times 2.2 \times 10^{-6} \text{ A}^2 \times H}{2 \times 3.3 \times 0.05 \sqrt{2}} = 6.67 \mu\text{F}$$

$$C_{SBB1\_min} = \frac{I_{P\_SBB1}^2 \times L}{2 \times V_{SBB1} \times \Delta V_{SBB1}} = \frac{0.5^2 \times 2.2 \times 10^{-6} \text{ A}^2 \times H}{2 \times 1.8 \times 0.03 \sqrt{2}} = 5.09 \mu\text{F}$$

$$C_{SBB2\_min} = \frac{I_{P\_SBB2}^2 \times L}{2 \times V_{SBB2} \times \Delta V_{SBB2}} = \frac{0.5^2 \times 2.2 \times 10^{-6} \text{ A}^2 \times H}{2 \times 1.2 \times 0.03 \sqrt{2}} = 7.64 \mu\text{F}$$

For this example, the 22 $\mu\text{F}$  GRM188R61A226ME15 is chosen for all three outputs. The effective capacitance after derating is the following:

$$C_{SBB0} = 8.113 \mu\text{F}$$

$$C_{SBB1} = 13.828 \mu\text{F}$$

$$C_{SBB2} = 16.793 \mu\text{F}$$

Go back to the calculator and enter the capacitance for each channel. [Figure 17](#) shows the expected ripples, which fit the requirements.

Figure 17. Component Selection—Expected Ripple

**Summary**

- $L = 1.5\mu\text{H}$
- $C_{\text{IN\_SBB}} = 22\mu\text{F}$
- Total Switching Utilization = 76%

**Table 8. Summary of Design for Component Selection Example**

	<b>SBB0</b>	<b>SBB1</b>	<b>SBB2</b>
$I_{\text{P\_SBBx}}$	0.75A	0.5A	0.5A
$C_{\text{SBBx}}$ (nominal)	22 $\mu\text{F}$	22 $\mu\text{F}$	22 $\mu\text{F}$
$\Delta V_{\text{SBBx}}$	33.4mV	23.0mV	24.8mV

Real applications should also consider the minimum input voltage since the battery discharges. The following is a summary using the same components but an input voltage of 3.0V instead. The switching utilization increased to 80.7%, slightly above 80%.

- $L = 1.5\mu\text{H}$
- $C_{\text{IN\_SBB}} = 22\mu\text{F}$
- Total Switching Utilization = 80.7%

**Table 9. Summary of Design with Lower Input Voltage**

	<b>SBB0</b>	<b>SBB1</b>	<b>SBB2</b>
$I_{\text{P\_SBBx}}$	0.75A	0.5A	0.5A
$C_{\text{SBBx}}$ (nominal)	22 $\mu\text{F}$	22 $\mu\text{F}$	22 $\mu\text{F}$
$\Delta V_{\text{SBBx}}$	36.3mV	28.8mV	28.4mV

**SIMO Switching Frequency**

The SIMO buck-boost regulator uses a pulse frequency modulation (PFM) control scheme. The switching frequency for each output is a function of the operating mode, input voltage, output voltage, load current, and inductance. Output capacitance is a minor factor in SIMO switching frequency. Maxim offers a SIMO calculator (see the [Support Material](#) section) to estimate expected switching frequency.

At no load, switching frequencies can be as low as 10Hz. For the 3.7V input to 1.2V output channel from the [Example Component Selection](#) section, the switching frequency is about 327kHz.

[Table 10](#) lists how different factors increase or decrease switching frequency.

**Table 10. Switching Frequency Control**

<b>FACTOR</b>	<b>INCREASING FREQUENCY</b>	<b>DECREASING FREQUENCY</b>
Inductor Current Peak Limit	Lower Peak Limit	Higher Peak Limit
Operating Mode	Buck-Boost Mode	Buck Mode
Inductor	Decrease Inductance	Increase Inductance
Output Capacitor	Decrease Capacitance	Increase Capacitance
Input Voltage	Higher Voltage	Lower Voltage
Output Voltage	Higher Voltage	Lower Voltage
Load Current	Higher Current	Lower Current

### Unused Outputs

Do not leave unused outputs unconnected. If an output left unconnected is accidentally enabled, the charged inductor experiences an open circuit, and the output voltage soars above the absolute maximum rating, damaging the device. If an output is not used, do one of the following:

1. Disable the output (CNFG\_SBBx\_B.EN\_SBBx[2:0] = 0x4 or 0x5) and connect the output to ground. If an unused output is default enabled or can be accidentally enabled, do one of the following recommendations instead.
2. Bypass the unused output with a 1 $\mu$ F capacitor to ground.
3. Connect the unused output to IN\_SBB or a different output channel if the unused output is programmed to a lower voltage. Since the output voltage is higher than the unused output, the regulator does not service the unused output even if it is unintentionally enabled.
  - Note that some OTP options have the active-discharge resistors enabled by default. Connecting an unused output to IN\_SBB is not recommended if the active discharge is enabled by default. If connecting the unused output to a different channel, disable the active-discharge resistor (CNFG\_SBBx\_B.ADE\_SBBx = 0) of the unused channel.

## PCB Layout Guide

### Capacitors

Place decoupling capacitors as close as possible to the IC such that connections from capacitor pads to pin and from capacitor pads to ground pins are short. Keeping the connections short lowers parasitic inductance and resistance, improving performance and shrinking the physical size of hot loops.

If connections to the capacitors are through vias, use multiple vias to minimize parasitics. Also, connect loads to the capacitor pads rather than the device pins.

Most critical are the capacitors for the switching regulator: input capacitor at IN\_SBB and output capacitors at SBBx.

### Input Capacitor at IN\_SBB

Minimize the parasitic inductance from PGND to input capacitor to IN\_SBB to reduce ringing on the LXA voltage.

### Output Capacitors at SBBx

The output capacitors experience large changes in current as the regulator charges (buck mode) and discharges (both modes) the inductor. In buck mode, the capacitor current ramps up at the same rate as mentioned in the previous section. In buck-boost mode, the capacitor current ramps up very quickly. In both modes, the capacitor current ramps down at a rate of  $\frac{dI_{C\_SBBx}}{dt} = \frac{V_{SBBx}}{L}$  from the inductor peak current. Since the ramp down can occur in less than 1 $\mu$ s, and the current increases rapidly for buck-boost mode, minimize parasitic inductance from SBBx to output capacitor to PGND.

### Inductor

Keep the inductor close to the IC to reduce trace resistance; however, prioritize any regulator input/output capacitors over the inductor. Use the appropriate trace width from LXA to inductor to LXB to support the peak inductor current. Likewise, if there are vias in the path, use an appropriate amount of vias to support the peak current.

### Ground Connections

As the switching regulator charges and discharges the inductor, current flows from PGND to the input capacitor ground, from output capacitor ground to PGND, or from output capacitor ground to input capacitor ground. Therefore, use a wide, continuous copper plane to connect PGND to the capacitor grounds.

When connecting the GND and PGND pins together, ensure noise from the power ground does not enter the analog ground (where GND is connected). For example, assuming the ground pins are connected through a solid ground plane on an internal layer, one via connecting GND to the internal ground plane can be sufficient to protect GND from most of the noise in the power-ground plane. Likewise, if there are other higher current or noisy circuitry near this device, avoid connecting the GND pin directly to their grounds.

For more guidelines on proper grounding, visit: <https://www.maximintegrated.com/en/design/partners-and-technology/design-technology/ground-layout-board-designers.html>.

## Detailed Description—Smart Power Selector Charger

The switching Li+ charger implements a power path with Maxim's Smart Power Selector. This allows separate input current limit and battery charge current settings. Batteries charge faster because of the headroom tracking provided by the SIMO buck-boost output. And with the supervision of the Smart Power Selector, the charge current is independently regulated and not shared with variable system loads. See the [Smart Power Selector](#) section for more information.

The programmable constant-current charge rate (7.5mA to 300mA) supports a wide range of battery capacities. The charger's programmable battery regulation voltage range (3.6V to 4.6V) supports a wide variety of cell chemistries. Small battery capacities are supported; the charger accurately terminates charging by detecting battery currents as low as 0.375mA.

To enhance charger safety, an NTC thermistor provides temperature monitoring in accordance with the JEITA recommendations. See the [Adjustable Thermistor Temperature Monitors](#) section for more information.

## Switching Charger Implementation with SIMO Architecture

When CHGIN voltage is higher than IN\_SBB, all internal circuits (AVL) and the SIMO regulator (PVL) are powered by CHGIN. SYS voltage is provided by the SBB3 output of the SIMO regulator.

To meet the required fast charge current capability, the peak inductor current limit has to be adjusted accordingly with CNFG\_SBB\_TOP\_B.IP\_SBB3[1:0].

## Charger Symbol Reference Guide

[Table 11](#) lists the names and functions of charger-specific signals and if they can be programmed through I<sup>2</sup>C serial communication. See the [Electrical Characteristics](#) and [Register Map](#) for more information.

**Table 11. Charger Quick Symbol Reference Guide**

SYMBOL	NAME	I <sup>2</sup> C PROGRAMMABLE?
V <sub>CHGIN_OVP</sub>	CHGIN overvoltage threshold	No
V <sub>CHGIN_UVLO</sub>	CHGIN undervoltage-lockout threshold	No
V <sub>SYS-MIN</sub>	Minimum SYS voltage regulation setpoint	No
V <sub>SYS_HDRM</sub>	SYS Headroom Voltage Regulation	No
V <sub>FAST-CHG</sub>	Fast-charge constant-voltage level	Yes, through CNFG_CHG_G.CHG_CV[5:0]
I <sub>FAST-CHG</sub>	Fast-charge constant-current level	Yes, through CNFG_CHG_G.E.CHG_CC[5:0]
I <sub>PQ</sub>	Prequalification current level	Yes, through CNFG_CHG_B.I_PQ
V <sub>PQ</sub>	Prequalification voltage threshold	Yes, through CNFG_CHG_C.CHG_PQ[2:0]
I <sub>TERM</sub>	Termination current level	Yes, through CNFG_CHG_C.I_TERM[1:0]
T <sub>J-REG</sub>	Die temperature regulation setpoint	Yes, through CNFG_CHG_D.TJ_REG[2:0]
t <sub>PQ</sub>	Prequalification safety timer	No
t <sub>FC</sub>	Fast-charge safety timer	Yes, through CNFG_CHG_E.T_FAST_CHG[1:0]
t <sub>TO</sub>	Top-off timer	Yes, through CNFG_CHG_C.T_TOPOFF[2:0]

[Figure 18](#) indicates the high-level functions of each control circuit within the battery-to-system switch.

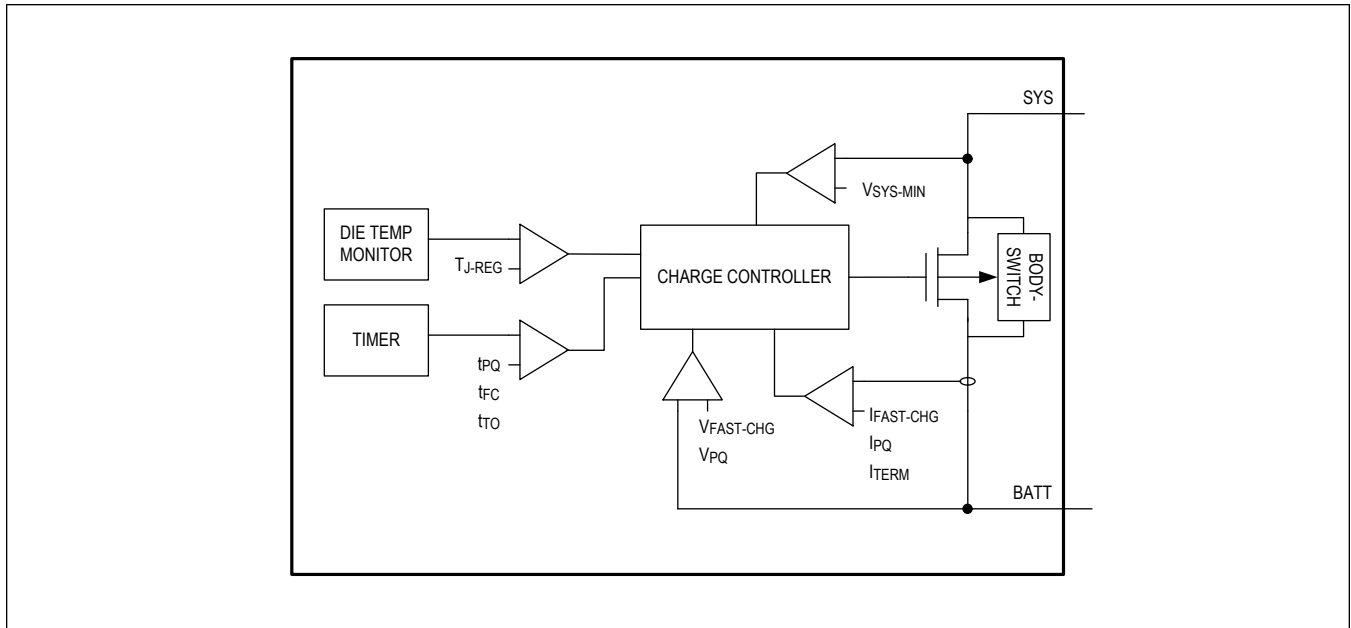

Figure 18.  $Q_{BAT}$  Control Loops

### Smart Power Selector

The Smart Power Selector seamlessly distributes power from the input (CHGIN) to the battery (BATT) and the system (SYS). The Smart Power Selector basic functions are:

- When the system load current is less than the SIMO output current capability, the battery is charged with residual power from SBB3\_CHG.
- When a valid input source is connected, the system regulates to  $V_{SYS\_MIN}$  or  $V_{BATT} + V_{SYS\_HDRM}$ , whichever is higher, to power system loads regardless of the battery's voltage (instant on).
- When the system load current exceeds SBB3 load current capability, the battery provides additional current to the system (supplement mode).
- When the battery is finished charging and an input source is present to power the system, the battery remains disconnected from the system.
- When the battery is connected and there is no input power, the system is powered from the battery.

### Die Temperature Regulation

If the die temperature exceeds  $T_{J\_REG}$  (programmed by  $CNFG\_CHG\_D.TJ\_REG[2:0]$ ) the charger attempts to limit the temperature increase by reducing the battery charge current. The  $STAT\_CHG\_A.TJ\_REG\_STAT$  bit asserts whenever charge current is reduced due to this loop. The charger's current sourcing capability to SYS remains unaffected when  $STAT\_CHG\_A.TJ\_REG\_STAT$  is high. A maskable interrupt ( $INT\_CHG.TJ\_REG\_I$ ) asserts to signal a change in  $STAT\_CHG\_A.TJ\_REG\_STAT$ . Use the  $INT\_CHG.TJ\_REG\_I$  interrupt to signal the system processor to reduce loads on SYS to reduce total system temperature.

### Charger State Machine

The battery charger follows a strict state-to-state progression to ensure that a battery is charged safely. The status bitfield  $STAT\_CHG\_B.CHG\_DTLS[3:0]$  reflects the charger's current operational state. A maskable interrupt ( $INT\_CHG.CHG\_I$ ) is available to signal a change in  $STAT\_CHG\_B.CHG\_DTLS[3:0]$ .

### Charger-Off State

The charger is off when CHGIN is invalid, the charger is disabled, or the battery is fresh.

CHGIN is invalid when the CHGIN input is invalid ( $V_{CHGIN} < V_{CHGIN\_UVLO}$  or  $V_{CHGIN} > V_{CHGIN\_OVP}$ ). While CHGIN is invalid, the battery is connected to the system. CHGIN voltage quality can be separately monitored by the STAT\_CHG\_B.CHGIN\_DTLS[1:0] status bitfield. See the [Register Map](#) section for details.

The charger is disabled when the charger enable bit is 0 (CNFG\_CHG\_B.CHG\_EN = 0). The battery is connected or disconnected to the system depending on the validity of  $V_{CHGIN}$  while CNFG\_CHG\_B.CHG\_EN = 0. See the [Smart Power Selector](#) section.

The battery is fresh when CHGIN is valid and the charger is enabled (CNFG\_CHG\_B.B.CHG\_EN = 1) and the battery is not low by  $V_{RESTART}$  ( $V_{BATT} > V_{FAST-CHG} - V_{RESTART}$ ). The battery is disconnected from the system and not charged while the battery is fresh. The charger state machine exits this state and begins charging when the battery becomes low by  $V_{RESTART}$  (100mV, typ). This condition is functionally similar to done state. See the [Done State](#) section.

### Prequalification State

The prequalification state is intended to assess a low-voltage battery's health by charging at a reduced rate. If the battery voltage is less than the  $V_{PQ}$  threshold, the charger is automatically in prequalification. If the cell voltage does not exceed  $V_{PQ}$  in 30 minutes ( $t_{PQ}$ ), the charger faults. The prequalification charge rate is a percentage of  $I_{FAST-CHG}$  and is programmable with CNFG\_CHG\_B.I\_PQ. The prequalification voltage threshold ( $V_{PQ}$ ) is programmable through CNFG\_CHG\_C.CHG\_PQ[2:0].

### Fast-Charge States

When the battery voltage is above  $V_{PQ}$ , the charger transitions to the fast-charge (CC) state. In this state, the charger delivers a constant current ( $I_{FAST-CHG}$ ) to the cell. The constant current level is programmable from 7.5mA to 300mA by CNFG\_CHG\_E.CHG\_CC[5:0].

When the cell voltage is below  $V_{SYS\_MIN} - V_{SYS\_HDRM}$ , SYS voltage is regulated to  $V_{SYS\_MIN}$  to stay above  $V_{SYS\_UVLO}$ ; when the cell voltage is above  $V_{SYS\_MIN} - V_{SYS\_HDRM}$  and below  $V_{FAST-CHG}$ , SYS voltage is regulated to  $V_{BATT} + V_{SYS\_HDRM}$  to minimize heat dissipation on the QBAT FET while maintaining sufficient headroom to regulate the charging current.

When the cell voltage reaches  $V_{FAST-CHG}$ , the charger state machine transitions to fast-charge (CV).  $V_{FAST-CHG}$  is programmable with CNFG\_CHG\_G.CHG\_CV[5:0] from 3.6V to 4.6V. The charger holds the battery's voltage constant at  $V_{FAST-CHG}$  while in the fast-charge (CV) state while maintaining the specified headroom voltage CNFG\_CHG\_D.VSYS\_HDRM between SYS and BATT. As the battery approaches full, the current accepted by the battery reduces. When the charger detects that the battery charge current has fallen below  $I_{TERM}$ , the charger state machine enters the top-off state.

A fast-charge safety timer starts when the state machine enters fast-charge (CC) or JEITA-modified fast-charge (CC) from a non-fast-charge state. The timer continues to run through all fast-charge states regardless of JEITA status. The timer length ( $t_{FC}$ ) is programmable from 3 hours to 7 hours in 2 hour increments with CNFG\_CHG\_E.T\_FAST\_CHG[1:0]. If it is desired to charge without a safety timer, program CNFG\_CHG\_E.T\_FAST\_CHG[1:0] with 0b00 to disable the feature. If the timer expires before the fast-charge states are exited, the charger faults. See the [Fast-Charge Timer Fault State](#) section for more information.

If the charge current falls below 20% of the programmed value during fast-charge (CC), the safety timer pauses. The timer also pauses for the duration of supplement mode events. The STAT\_CHG\_B.TIME\_SUS bit indicates the status of the fast-charge safety timer. See the [Register Map](#) section for more details.

### Headroom Control

To reduce heat dissipation over the QBAT FET, headroom voltage tracking is implemented by the charging output of the SIMO regulator to minimize the voltage drop over the the QBAT FET while providing enough headroom to regulate the charging current. The headroom voltage is specified by CNFG\_CHG\_D.VSYS\_HDRM. It can be programmed to be 150mV or 200mV. See the [Typical Charge Profile](#) for the illustration of the headroom tracking implementation during fast charging process.

### Top-Off State

The top-off state is entered when the battery charge current falls below  $I_{TERM}$  during the fast-charge (CV) state.  $I_{TERM}$  is a percentage of  $I_{FAST-CHG}$  and is programmable through `CNFG_CHG_C.I_TERM[1:0]`. While in the top-off state, the battery charger continues to hold the battery's voltage at  $V_{FAST-CHG}$ . A programmable top-off timer starts when the charger state machine enters the top-off state. When the timer expires, the charger enters the done state. The top-off timer value ( $t_{TO}$ ) is programmable from 0 minutes to 35 minutes with `CNFG_CHG_C.T_TOPOFF[2:0]`. If it is desired to stop charging as soon as battery current falls below  $I_{TERM}$ , program  $t_{TO}$  to 0 minutes.

### Done State

The charger enters the done state when the top-off timer expires. The battery remains disconnected from the system during done. The charger restarts if the battery voltage falls more than  $V_{RESTART}$  (100mV, typ) below the programmed  $V_{FAST-CHG}$  value.

### Prequalification Timer Fault State

The prequalification timer fault state is entered when the battery's voltage fails to rise above  $V_{PQ}$  in  $t_{TO}$  (30 minutes, typ) from when the prequalification state was first entered. If a battery is too deeply discharged, damaged, or internally shorted, the prequalification timer fault state can occur. During the timer fault state, the charger stops delivering current to the battery and the battery remains disconnected from the system. To exit the prequalification timer fault state, toggle the charger enable (`CNFG_CHG_B.CHG_EN`) bit or unplug and replug the external voltage source connected to CHGIN.

### Fast-Charge Timer Fault State

The charger enters the fast-charge timer fault state if the fast-charge safety timer expires. While in this state, the charger stops delivering current to the battery and the battery remains disconnected from the system. To exit the fast-charge timer fault state, toggle the charger enable bit (`CNFG_CHG_B.CHG_EN`) or unplug and replug the external voltage source connected to CHGIN.

### Battery Temperature Fault State

If the thermistor monitoring circuit reports that the battery is either too hot or too cold to charge (as programmed by `CNFG_CHG_A.THM_HOT[1:0]` and `CNFG_CHG_A.THM_COLD[1:0]`), the state machine enters the battery temperature fault state. While in this state, the charger stops delivering current to the battery and the battery remains disconnected from the system. This state can only be entered if the thermistor is enabled (`CNFG_CHG_F.THM_EN = 1`). The battery temperature fault state has priority over any other fault state and can be exited when the thermistor is disabled (`CNFG_CHG_F.THM_EN = 0`) or when the battery returns to an acceptable temperature. When this fault state is exited, the state machine returns to the last state it was in before the battery temperature fault state was entered.

All active charger timers (fast-charge safety timer, prequalification timer, or top-off timer) are paused in this state. When the charger exits this state, the prequalification timer resumes while the fast-charge safety and top-off timers reset.

The `STAT_CHG_A.THM_DTLS[2:0]` bitfield reports battery temperature status. See the [Adjustable Thermistor Temperature Monitors](#) and the [Register Map](#) sections for more information.

### JEITA-Modified States

If the thermistor is enabled (`CNFG_CHG_F.THM_EN = 1`), then the charger state machine is allowed to enter the JEITA-modified states. These states are entered if the charger's temperature monitors indicate that the battery temperature is either warm (greater than  $T_{WARM}$ ) or cool (lesser than  $T_{COOL}$ ). See the [Adjustable Thermistor Temperature Monitors](#) section for more information about setting the temperature thresholds.

The charger's current and voltage parameters change from  $I_{FAST-CHG}$  and  $V_{FAST-CHG}$  to  $I_{FAST-CHG\_JEITA}$  and  $V_{FAST-CHG\_JEITA}$  while in the JEITA-modified states. The JEITA modified parameters can be independently set to lower voltage and current values so that the battery can charge safely over a wide range of ambient temperatures. If the battery temperature returns to normal, or the thermistor is disabled (`CNFG_CHG_.THM_EN = 0`), the charger exits the JEITA-modified states.

### Typical Charge Profile

A typical battery charge profile (and state progression) is illustrated in [Figure 20](#).

Figure 20. Example Charge Profile

## Charger Applications Information

### CHGIN/SYS/BATT Capacitor Selection

Bypass CHGIN to GND with a 47 $\mu$ F ceramic capacitor to minimize input voltage ripple. Larger values increase decoupling for the linear charger but increase inrush current from the DC charge source when the product/IC is first connected to a source through a cable/plug. If the DC charging source is an upstream USB device, limit the maximum CHGIN input capacitance based on the appropriate USB specification (considering voltage derating of the capacitors, the typical effective capacitance should be no more than 10 $\mu$ F). Bypass SYS to GND with a 22 $\mu$ F ceramic capacitor. This capacitor ensures the stability of SYS while it is regulated from CHGIN. Larger values of SYS capacitance increase decoupling for all SYS loads. The effective value of the SYS capacitor must be greater than 4 $\mu$ F and no more than 100 $\mu$ F. See the [Output Capacitor Selection](#) section for more details.

Bypass BATT to GND with a 4.7 $\mu$ F ceramic capacitor. This capacitor stabilizes the BATT voltage regulation loop. The effective value of the BATT capacitor must be greater than 1 $\mu$ F.

Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients. All ceramic capacitors derate with DC bias voltage (effective capacitance goes down as DC bias goes up). Generally, small case size capacitors derate heavily compared to larger case sizes (0603 case size performs better than 0402). Consider the effective capacitance value carefully by consulting the manufacturer's data sheet.

### Detailed Description—Adjustable Thermistor Temperature Monitors

The optional use of a negative temperature coefficient (NTC) thermistor (thermally coupled to the battery) enables the charger to operate safely over the JEITA temperature range. When the thermistor is enabled (CNFG\_CHG\_F.THM\_EN = 1), the charger continuously monitors the voltage at the THM pin to sense the temperature of the battery being charged.

See [Figure 21](#) for a visual example of the following:

- If the battery temperature is higher than  $T_{COOL}$  and lower than  $T_{WARM}$ , the battery charges normally with the normal values for  $V_{FAST-CHG}$  and  $I_{FAST-CHG}$ . The charger state machine does not enter JEITA-modified states while the battery temperature is normal.
- If the battery temperature is either above  $T_{WARM}$  but below  $T_{HOT}$ , or, below  $T_{COOL}$  but above  $T_{COLD}$ , the battery charges with the JEITA-modified voltage and current values. These modified values,  $V_{FAST-CHG\_JEITA}$  and  $I_{FAST-CHG\_JEITA}$ , are programmable through CNFG\_CHG\_H.CHG\_CV\_JEITA[5:0] and CNFG\_CHG\_F.CHG\_CC\_JEITA[5:0], respectively. These values are independently programmable from the unmodified  $V_{FAST-CHG}$  and  $I_{FAST-CHG}$  values and can even be programmed to the same values if an automatic response to a warm or cool battery is not desired. The charger state machine enters JEITA-modified states while the battery temperature is outside of normal.
- If the battery temperature is either above  $T_{HOT}$  or below  $T_{COLD}$ , the charger follows the JEITA recommendation and pauses charging. The charger state machine enters battery temperature fault state while charging is paused due to extremely high or low temperatures.

The battery's temperature status is reflected by the STAT\_CHG\_A.THM\_DTLS[2:0] status bitfield. A maskable interrupt (INT\_CHG.THM\_I) signals a change in status. See the [Register Map](#) for more information. To completely disable the charger's automatic response to battery temperature, disable the feature by programming CNFG\_CHG\_F.THM\_EN = 0.

Figure 21. Safe-Charging Profile Example

The voltage thresholds corresponding to the JEITA temperature thresholds are independently programmable through CNFG\_CHG\_A.THM\_HOT[1:0], CNFG\_CHG\_A.THM\_WARM[1:0], CNFG\_CHG\_A.THM\_COOL[1:0], and CNFG\_CHG\_A.THM\_COLD[1:0]. Each threshold can be programmed to one of four voltage options spanning 15°C for an NTC beta of 3380K. See the [Configurable Temperature Thresholds](#) section and the [Register Map](#) for more information.

### Thermistor Bias

An external ADC can optionally perform conversions on the THM and TBIAS pins to measure the battery's temperature. An on-chip analog multiplexer is used to route these nodes to the AMUX pin. The operation of the analog multiplexer does not interfere with the charger's temperature monitoring comparators or the charger's automatic JEITA response. See the [Analog Multiplexer](#) section for more information.

The NTC thermistor's bias source (TBIAS) is outlined as follows:

- If CHGIN is valid and the thermistor is enabled (CNFG\_CHG\_F.THM\_EN = 1), the thermistor is biased, so the charger can automatically respond to battery temperature changes.
- If the analog multiplexer connects THM or TBIAS to AMUX, then the thermistor is biased, so an external ADC can perform a meaningful temperature conversion.

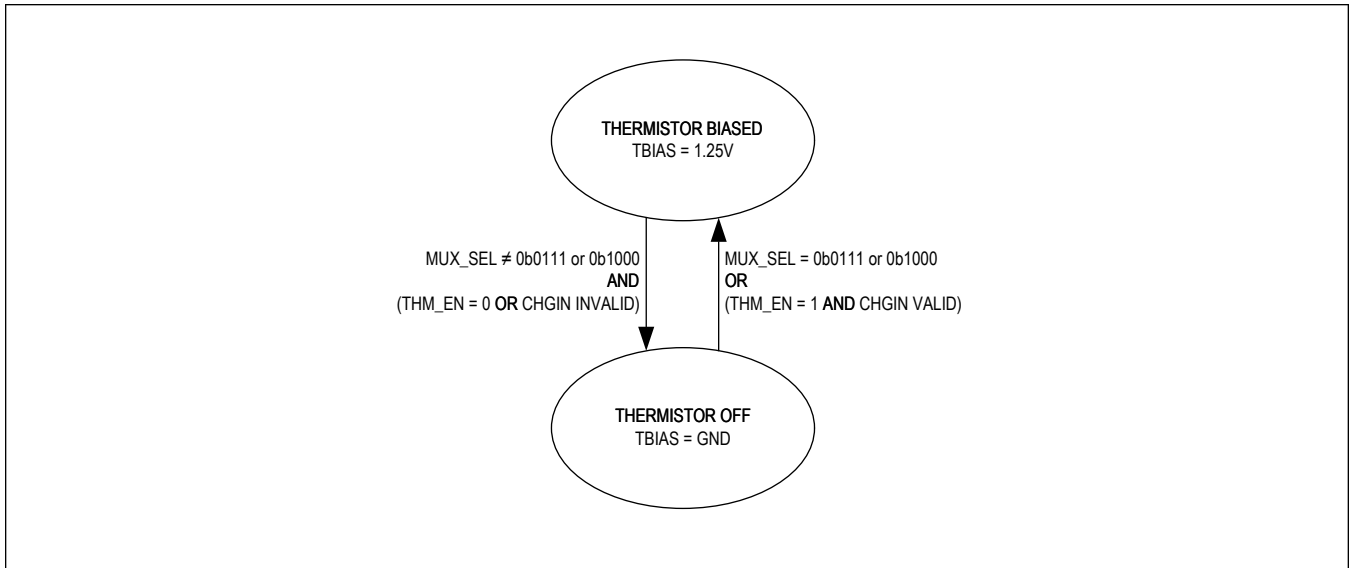

Figure 22. Thermistor Bias State Diagram

The AMUX pin is a buffered output. The operation of the analog multiplexer and external ADC does not collide with the function of the on-chip temperature monitors. Both functions can be used simultaneously with no ill effect.

**Configurable Temperature Thresholds**

Temperature thresholds for different NTC thermistor beta values are listed in Table 12. The largest possible programmable temperature range can be realized by using an NTC with a beta of 3380K. Using a larger beta compresses the temperature range. The trip voltage thresholds are programmable with the CNFG\_CHG\_A.THM\_HOT[1:0], CNFG\_CHG\_A.THM\_WARM[1:0], CNFG\_CHG\_A.THM\_COOL[1:0], and CNFG\_CHG\_A.THM\_COLD[1:0] bitfields. All possible programmable trip voltages are listed in Table 12.

**Table 12. Trip Temperatures vs. Trip Voltages for Different NTC β**

TRIP VOLTAGE (V)	TRIP TEMPERATURES (°C)					
	3380K	3435K	3940K	4050K	4100K	4250K
1.024	-10.0	-9.5	-5.6	-4.8	-4.5	-3.5
0.976	-5.0	-4.6	-1.1	-0.5	-0.2	0.6
0.923	0.0	0.3	3.3	3.8	4.1	4.8
0.867	5.0	5.3	7.7	8.1	8.3	8.9
0.807	10.0	10.2	12.0	12.4	12.5	12.9
0.747	15.0	15.1	16.4	16.6	16.7	17.0
0.511	35.0	34.8	33.5	33.3	33.2	32.9
0.459	40.0	39.8	37.8	37.4	37.3	36.8
0.411	45.0	44.7	42.0	41.5	41.3	40.7
0.367	50.0	49.6	46.2	45.6	45.3	44.6
0.327	55.0	54.5	50.4	49.7	49.3	48.4
0.291	60.0	59.4	54.6	53.7	53.3	52.2

These are theoretical values computed by a formula. Refer to the particular NTC's data sheet for more accurate measured data. In all cases, select the value of R<sub>BIAS</sub> to be equal to the NTC's effective resistance at +25°C.

**Applications Information**

**Using Different Thermistor  $\beta$**

If an NTC with a beta larger than 3380K is used and the resulting available programmable temperature range is undesirably small, then two adjusting resistors can be used to expand the temperature range.  $R_S$  and  $R_P$  can be optionally added to the NTC thermistor circuit shown in [Figure 23](#) to expand the range of programmable temperature thresholds.

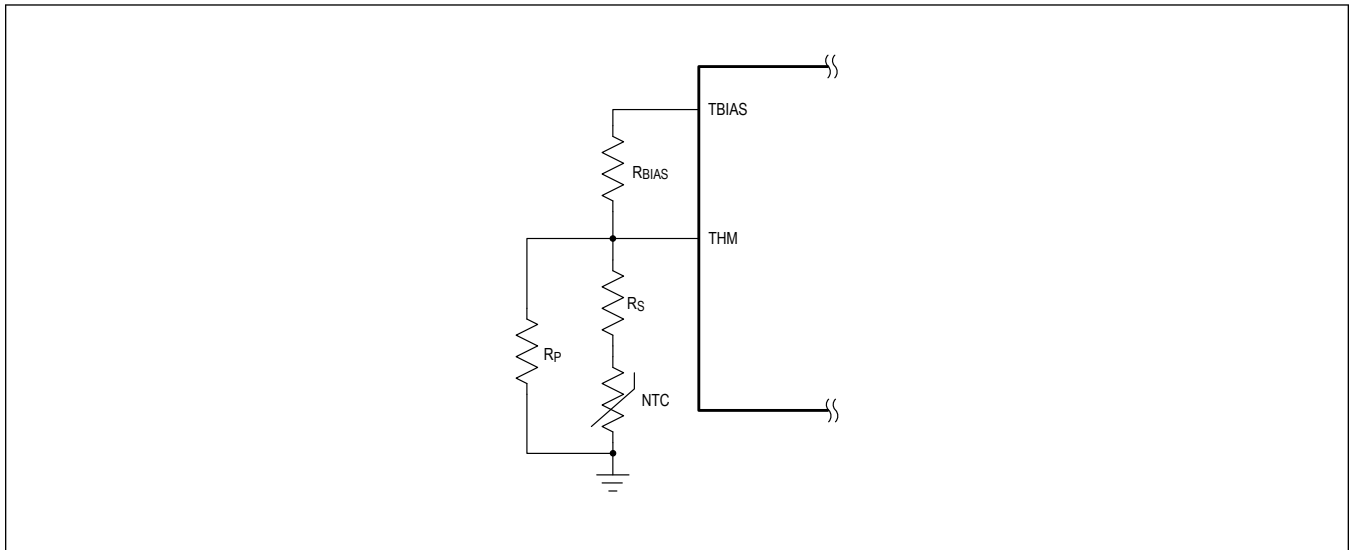

Figure 23. Thermistor Circuit with Adjusting Series and Parallel Resistors

Select values for  $R_S$  and  $R_P$  based on the information shown in [Table 13](#).

**Table 13. Example  $R_S$  and  $R_P$  Correcting Values for NTC  $\beta$  Above 3380K**

PARAMETER	UNIT	TARGET NTC CASE	CASE 1		CASE 2		CASE 3	
NTC Thermistor Beta	K	3380	3940		4050		4250	
25°C NTC Resistance	k $\Omega$	10	10		47		100	
$R_{BIAS}$		10	10		47		100	
Adjusting Parallel Resistor, $R_P$		Open	Open	200	Open	680	Open	1300
Adjusting Series Resistor, $R_S$		Short	Short	0.62	Short	3.3	Short	9.1
$R_{NTC}$ at 1.024V <sub>COOLD</sub> Threshold		45.24	45.24	578.5	212.6	306.1	452.4	684.8
$R_{NTC}$ at 0.867V <sub>COOL</sub> Threshold		22.61	22.61	248.8	106.3	122.7	226.1	264.7
$R_{NTC}$ at 0.459V <sub>WARM</sub> Threshold		5.81	5.81	5.36	27.3	25.1	58.1	51.7
$R_{NTC}$ at 0.291V <sub>HOT</sub> Threshold		3.04	3.04	2.46	14.3	112.7	30.4	22.0

### Detailed Description—Analog Multiplexer

An external ADC can be used to measure the chip's various signals for general functionality or on-the-fly power monitoring. The CNFG\_CHG\_I.MUX\_SEL[3:0] bitfield controls the internal analog multiplexer responsible for connecting the proper channel to the AMUX pin. Each measurable signal is listed in [Table 15](#) with its appropriate multiplexer channel.

The voltage on the AMUX pin is a buffered output that ranges from 0V to VFS (1.25V, typ). The buffer has 50 $\mu$ A of quiescent current consumption and is only active when a channel is selected (CNFG\_CHG\_I.MUX\_SEL[3:0]  $\neq$  0b0000). Disable the buffer by programming CNFG\_CHG\_I.MUX\_SEL[3:0] to 0b0000 when not actively converting the voltage on AMUX. The AMUX output is high-impedance while CNFG\_CHG\_I.MUX\_SEL[3:0] is 0b0000.

[Table 15](#) shows how to translate the voltage signal on the AMUX pin to the value of the parameter being measured. See the [Electrical Characteristics](#) table and the [Register Map](#) for more details.

**Table 15. AMUX Signal Transfer Functions**

SIGNAL	MUX_SEL[3:0]	TRANSFER FUNCTION	FULL-SCALE SIGNAL MEANING (V <sub>AMUX</sub> = 1.25V)	ZERO-SCALE SIGNAL MEANING (V <sub>AMUX</sub> = 0V)
CHGIN Pin Voltage	0b0001	$V_{CHGIN} = \frac{V_{AMUX}}{G_{VCHGIN}}$	7.5V	0V
BATT Pin Voltage	0b0011	$V_{BATT} = \frac{V_{AMUX}}{G_{VBATT}}$	4.6V	0V
BATT Pin Charging Current	0b0100	$I_{BATT(CHG)} = \frac{V_{AMUX}}{V_{FS}} \times I_{FAST-CHG}$	100% of I <sub>FAST-CHG</sub> (CHG_CC[5:0])	0% of I <sub>FAST-CHG</sub>
BATT Pin Discharge Current	0b0101	$I_{BATT(DISCHG)} = \frac{(V_{AMUX} - V_{NULL})}{(V_{FS} - V_{NULL})} \times I_{DISCHG-SCALE}$	100% of I <sub>DISCHG-SCALE</sub> (IMON_DISCHG_SCALE[3:0])	0% of I <sub>DISCHG-SCALE</sub>
BATT Pin Discharge Current NULL	0b0110	$V_{NULL} = V_{AMUX}$	1.25V	0V

**Table 15. AMUX Signal Transfer Functions (continued)**

SIGNAL	MUX_SEL[3:0]	TRANSFER FUNCTION	FULL-SCALE SIGNAL MEANING (V <sub>AMUX</sub> = 1.25V)	ZERO-SCALE SIGNAL MEANING (V <sub>AMUX</sub> = 0V)
THM Pin Voltage	0b0111	$V_{THM} = V_{AMUX}$	1.25V	0V
TBIAS Pin Voltage	0b1000	$V_{TBIAS} = V_{AMUX}$	1.25V	0V
AGND Pin Voltage*	0b1001	$V_{AGND} = V_{AMUX}$	1.25V	0V
SYS Pin Voltage	0b1010	$V_{SYS} = \frac{V_{AMUX}}{G_{V_{SYS}}}$	4.8V	0V

\*AGND pin voltage is accessed through a 100Ω (typ) pulldown resistor.

### Measuring Battery Current

Sampling current in the BATT pin is possible at any time or in any mode with an external ADC. For improved accuracy, the analog circuitry used for monitoring battery discharge current is different from the circuitry monitoring battery charge current. [Table 16](#) outlines how to determine the direction of battery current.

**Table 16. Battery Current Direction Decode**

MEASUREMENT	CHARGING OR DISCHARGING INDICATORS		
	STAT_CHG_B.CHG	STAT_CHG_B.CHG_DTLS[3:0]	STAT_CHG_B.CHGIN_DTLS[1:0]
Discharging Battery Current (Positive Battery Terminal Sourcing Current)	<i>Don't care</i>	<i>Don't care</i>	0b00 0b01 0b10
Charging Battery Current (Positive Battery Terminal Sinking Current)	1	0b0001 to 0b0111	0b11

### Method for Measuring Discharge Current

1. Program the multiplexer to switch to the discharge NULL measurement by changing CNFG\_CHG\_I.MUX\_SEL[3:0] to 0b0110. A NULL conversion must always be performed first to cancel offsets.
2. Wait the appropriate channel switching time (0.3μs, typ).
3. Convert the voltage on the AMUX pin and store as V<sub>NULL</sub>.
4. Program the multiplexer to switch to the battery discharge current measurement by changing CNFG\_CHG\_I.MUX\_SEL[3:0] to 0b0101. A nonnulling conversion should be done immediately after a NULL conversion.
5. Wait the appropriate channel switching time (0.3μs, typ).
6. Convert the voltage on the AMUX pin and use the following transfer function to determine the discharge current:

$$I_{BATT(DISCHG)} = \frac{(V_{AMUX} - V_{NULL})}{(V_{FS} - V_{NULL})} \times I_{DISCHG-SCALE}$$

V<sub>FS</sub> is 1.25V typical. I<sub>DISCHG-SCALE</sub> is programmable through CNFG\_CHG\_I.IMON\_DISCHG\_SCALE[3:0]. The default value is 300mA. If smaller currents are anticipated, then I<sub>DISCHG-SCALE</sub> can be reduced for improved measurement accuracy.

### Method for Measuring Charge Current

1. Program the multiplexer to switch to the charge current measurement by changing CNFG\_CHG\_I.MUX\_SEL[3:0] to 0b0100.
2. Wait the appropriate channel switching time (0.3μs, typ).
3. Convert the voltage on the AMUX pin and use the following transfer function to determine charging current.

$$I_{\text{BATT(CHG)}} = \frac{V_{\text{AMUX}}}{V_{\text{FS}}} \times I_{\text{FAST-CHG}}$$

$V_{\text{FS}}$  is 1.25V typical.  $I_{\text{FAST-CHG}}$  is the charger's fast-charge constant-current setting and is programmable through CNFG\_CHG\_E.CHG\_CC[5:0].

### Detailed Description—Low-Dropout Linear Regulator (LDO)/Load Switch (LSW)

The device includes one low-dropout linear regulator (LDO) that can also be configured as a load switch. The LDO is optimized to have a low quiescent current. The input voltage range ( $V_{\text{IN\_LDOx}}$ ) allows it to be powered directly from the main energy source such as a Li-Poly battery or from an intermediate regulator. The linear regulator delivers up to 100mA.

### Features and Benefits

- 100mA LDO
- LDO Input Voltage Range: 1.71V to 5.5V
- LDO Output Voltage Range: 0.5V to 5.0V
- LSW Input Voltage Range: 1.3V to 5.5V
- Adjustable Output Voltage
- 100mV Maximum Dropout Voltage at ECT Conditions
- Programmable On-Chip Active Discharge

### LDO/LSW Simplified Block Diagram

The LDO/LSW block has one input (IN\_LDO) and one output (LDO) and several ports that exchange information with the rest of the device ( $V_{\text{REF}}$ , EN\_LDO, ADE\_LDO).  $V_{\text{REF}}$  comes from the main bias circuits. CNFG\_LDO0\_B.EN\_LDO and CNFG\_LDO0\_B.ADE\_LDO are register bits for controlling the enable and active-discharge feature, respectively. See the [Register Map](#) for more information.

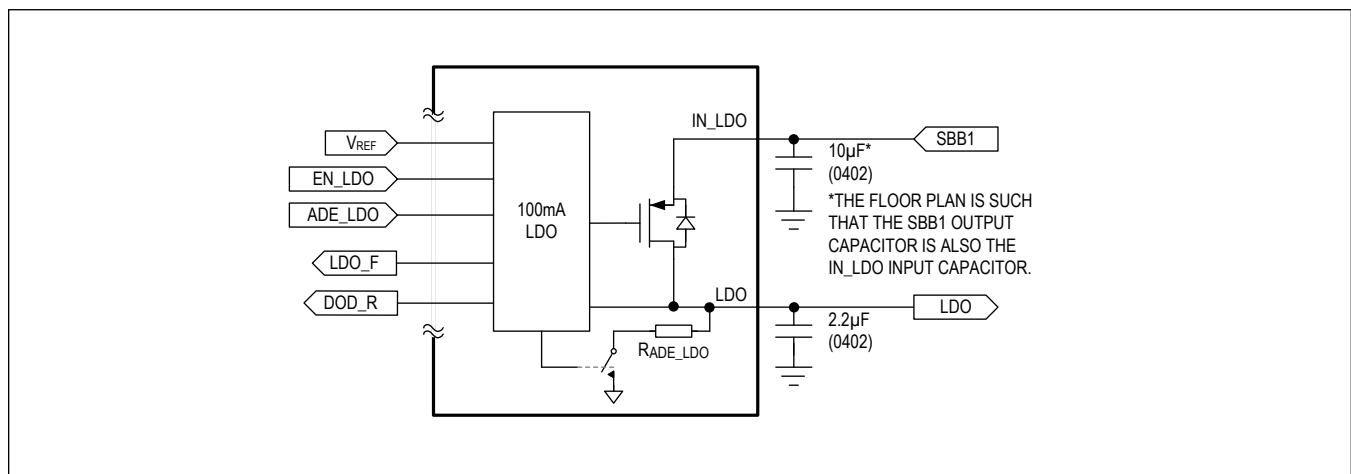

Figure 24. LDO Simplified Block Diagram

### LDO/LSW Active-Discharge Resistor

Each LDO/LSW block has an active-discharge resistor ( $R_{AD\_LDO}$ ) that is enabled if  $CNFG\_LDO\_B.ADE\_LDO = 1$  and LDO is disabled. Enabling the active discharge feature helps ensure a complete and timely power down of the resource. During power-up, if  $V_{SYS} > V_{POR}$  and  $CNFG\_LDO\_B.ADE\_LDO = 1$ , the active-discharge resistor is enabled.

### LDO/LSW Soft-Start

The soft-start feature limits inrush current during startup and is achieved by limiting the slew rate of the output voltage during startup ( $dV_{OUT\_LDO}/dt_{SS}$ ).

More output capacitance results in higher input current surges during startup. The following equation and example describes the input current surge phenomenon during startup.

The input current ( $I_{IN\_LDO}$ ) during soft-start is:

$$I_{IN\_LDO} = C_{LDO} \frac{dV_{OUT\_LDO}}{dt_{SS}} + I_{OUT\_LDO}$$

where:

- $C_{LDO}$  is the capacitance on the output of the regulator
- $dV_{OUT\_LDO}/dt_{SS}$  is the voltage change rate of the output

For example, given the following conditions, the input current ( $I_{IN\_LDO}$ ) during soft-start is 13.08mA:

Given:

- $C_{LDO} = 2.2\mu\text{F}$
- $dV_{OUT\_LDO}/dt_{SS} = 1.4\text{mV}/\mu\text{s}$
- LDO programmed to 1.85V
- $R_{LDO} = 185\Omega$  ( $I_{OUT\_LDO} = 1.85\text{V}/185\Omega = 10\text{mA}$ )

Calculation:

- $I_{IN} = 2.2\mu\text{F} \times 1.4\text{mV}/\mu\text{s} + 10\text{mA}$
- $I_{IN} = 13.08\text{mA}$

### Load Switch Configuration

The LDO can be configured as load switches with the  $CNFG\_LDO0\_B.LDO\_MD$  bit. As shown in [Figure 25](#), the transition from LDO to LSW mode is controlled by a defined slew-rate until dropout is detected. Once dropout is detected, the load switch is fully closed and the dropout interrupt flag ( $INT\_GLBL0.DOD\_R$ ) is set.

Figure 25. LDO to LSW Transition Waveform

## Applications Information

### Input Capacitor Selection

Make sure the input bypass capacitance ( $C_{IN\_LDO}$ ) is at least  $2.2\mu\text{F}$ . Larger values of  $C_{IN\_LDO}$  improve the decoupling for LDO. The floor plan of the device is such that SBB1 is adjacent to IN\_LDO and if the SIMO channel 1 output powers the input of LDO, then its output capacitor ( $C_{SBB1}$ ) can also serve as  $C_{IN\_LDO}$  such that only one capacitor is required.

$C_{IN\_LDO}$  reduces the current peaks drawn from the battery or input power source during operation. The impedance of the input capacitor (ESR, ESL) should be very low (i.e.,  $\text{ESR} \leq 50\text{m}\Omega$  and  $\text{ESL} \leq 5\text{nH}$ ) for frequencies up to  $0.5\text{MHz}$ . Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients.

### Output Capacitor Selection

For both LDO and LSW modes, choose the output bypass capacitance ( $C_{LDO}$ ) to be  $1\mu\text{F}$ .

In LDO mode, larger values of  $C_{LDO}$  improve output PSRR but increase input surge currents during soft-start and output voltage changes. The effective output capacitance should not exceed  $2.8\mu\text{F}$  to maintain stability.

While in LDO mode,  $C_{LDO}$  is required to keep stability. The series inductance of the output capacitor and its series resistance should be low (i.e.,  $\text{ESR} \leq 10\text{m}\Omega$  and  $\text{ESL} \leq 1\text{nH}$ ) for frequencies up to  $0.5\text{MHz}$ . Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients.

A capacitor's effective capacitance decreases with increased DC bias voltage. This effect is more pronounced with smaller capacitor case sizes. Due to this characteristic, 0603 case size capacitors tend to perform well while 0402 case size capacitors of the same value perform poorly.

## Detailed Description—I<sup>2</sup>C Serial Communication

### General Description

The IC features a revision 3.0 I<sup>2</sup>C-compatible, 2-wire serial interface consisting of a bidirectional serial data line (SDA) and a serial clock line (SCL). This device acts as a slave-only device, relying on the master to generate a clock signal. SCL clock rates from 0Hz to 3.4MHz are supported.

I<sup>2</sup>C is an open-drain bus and therefore SDA and SCL require pullups. Optional resistors (24Ω) in series with SDA and SCL protect the device inputs from high-voltage spikes on the bus lines. Series resistors also minimize crosstalk and undershoot on bus signals.

Figure 26 shows the simplified diagram for the I<sup>2</sup>C based communications controller. For additional information on I<sup>2</sup>C, refer to the *I<sup>2</sup>C Bus Specification and User Manual* which is available for free through the internet.

### Features

- I<sup>2</sup>C Revision 3.0 Compatible Serial Communications Channel
- 0Hz to 100kHz (Standard Mode)
- 0Hz to 400kHz (Fast Mode)
- 0Hz to 1MHz (Fast-Mode Plus)
- 0Hz to 3.4MHz (High-Speed Mode)
- Does not utilize I<sup>2</sup>C Clock Stretching

### I<sup>2</sup>C Simplified Block Diagram

There are three pins (aside from GND) for the I<sup>2</sup>C-compatible interface. V<sub>IO</sub> determines the logic level, SCL is the clock line, and SDA is the data line. Note that the interface does **not** have the ability to drive the SCL line.

Figure 26. I<sup>2</sup>C Simplified Block Diagram

## I<sup>2</sup>C System Configuration

The I<sup>2</sup>C-compatible interface is a multimaster bus. The maximum number of devices that can attach to the bus is only limited by bus capacitance.

A device on the I<sup>2</sup>C bus that sends data to the bus is called a transmitter. A device that receives data from the bus is called a receiver. The device that initiates a data transfer and generates the SCL clock signals to control the data transfer is a master. Any device that is being addressed by the master is considered a slave. The I<sup>2</sup>C-compatible interface operates as a slave on the I<sup>2</sup>C bus with transmit and receive capabilities.

Figure 27. I<sup>2</sup>C System Configuration

## I<sup>2</sup>C Interface Power

The I<sup>2</sup>C interface derives its power from  $V_{IO}$ . Typically a power input such as  $V_{IO}$  would require a local 0.1 $\mu$ F ceramic bypass capacitor to ground. However, in highly integrated power distribution systems, a dedicated capacitor might not be necessary. If the impedance between  $V_{IO}$  and the next closest capacitor ( $\geq 0.1\mu$ F) is less than 100m $\Omega$  in series with 10nH, then a local capacitor is not needed. Otherwise, bypass  $V_{IO}$  to GND with a 0.1 $\mu$ F ceramic capacitor.

$V_{IO}$  accepts voltages from 1.7V to 3.6V ( $V_{IO}$ ). Cycling  $V_{IO}$  does not reset the I<sup>2</sup>C registers. When  $V_{IO}$  is less than  $V_{IOUVLO}$  and  $V_{SYS}$  is less than  $V_{SYSUVLO}$ , SDA and SCL are high-impedance.

## I<sup>2</sup>C Data Transfer

One data bit is transferred during each SCL clock cycle. The data on SDA must remain stable during the high period of the SCL clock pulse. Changes in SDA while SCL is high are control signals. See the [I<sup>2</sup>C Start and Stop Conditions](#) section. Each transmit sequence is framed by a start (S) condition and a stop (P) condition. Each data packet is nine bits long: eight bits of data followed by the acknowledge bit. Data is transferred with the MSB first.

## I<sup>2</sup>C Start and Stop Conditions

When the serial interface is inactive, SDA and SCL idle high. A master device initiates communication by issuing a start condition. A start condition is a high-to-low transition on SDA with SCL high. A stop condition is a low-to-high transition on SDA, while SCL is high. See [Figure 28](#).

A start condition from the master signals the beginning of a transmission to the device. The master terminates transmission by issuing a not-acknowledge followed by a stop condition (see the [I<sup>2</sup>C Acknowledge Bit](#) section for information on not-acknowledge). The stop condition frees the bus. To issue a series of commands to the slave, the master can issue repeated start (Sr) commands instead of a stop command to maintain control of the bus. In general a repeated start command is functionally equivalent to a regular start command.

Figure 28. I<sup>2</sup>C Start and Stop Conditions

**I<sup>2</sup>C Acknowledge Bit**

Both the I<sup>2</sup>C bus master and slave devices generate acknowledge bits when receiving data. The acknowledge bit is the last bit of each nine bit data packet. To generate an acknowledge (A), the receiving device must pull SDA low before the rising edge of the acknowledge-related clock pulse (ninth pulse) and keep it low during the high period of the clock pulse. See Figure 29. To generate a not-acknowledge (nA), the receiving device allows SDA to be pulled high before the rising edge of the acknowledge-related clock pulse and leaves it high during the high period of the clock pulse.

Monitoring the acknowledge bits allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master should reattempt communication at a later time.

This device issues an ACK for all register addresses in the possible address space even if the particular register does not exist.

Figure 29. Acknowledge Bit

**I<sup>2</sup>C Slave Address**

The I<sup>2</sup>C controller implements 7-bit slave addressing. An I<sup>2</sup>C bus master initiates communication with the slave by issuing a START condition followed by the slave address. See Figure 30. The OTP address is factory-programmable for one of two options. See Table 17. All slave addresses not mentioned in Table 17 are not acknowledged.

**Table 17. I<sup>2</sup>C Slave Address Options**

ADDRESS	7-BIT SLAVE ADDRESS	8-BIT WRITE ADDRESS	8-BIT READ ADDRESS
Main Address (ADDR = 1)*	0x48, 0b 100 1000	0x90, 0b 1001 0000	0x91, 0b 1001 0001
Main Address (ADDR = 0)*	0x40, 0b 100 0000	0x80, 0b 1000 0000	0x81, 0b 1000 0001
Test Mode**	0x49, 0b 100 1001	0x92, 0b 1001 0010	0x93, 0b 1001 0011

\*Perform all reads and writes on the main address. ADDR is a factory one-time programmable (OTP) option, allowing for address changes in the event of a bus conflict. [Contact Maxim](#) for more information.

\*\*When test mode is unlocked, the additional address is acknowledged. Test mode details are confidential. If possible, leave the test mode address unallocated to allow for the rare event that debugging needs to be performed in cooperation with Maxim.

Figure 30. Slave Address Example

### I<sup>2</sup>C Clock Stretching

In general, the clock signal generation for the I<sup>2</sup>C bus is the responsibility of the master device. The I<sup>2</sup>C specification allows slow slave devices to alter the clock signal by holding down the clock line. The process in which a slave device holds down the clock line is typically called clock stretching. The IC does not use any form of clock stretching to hold down the clock line.

### I<sup>2</sup>C General Call Address

This device does not implement the I<sup>2</sup>C specifications general call address and does not acknowledge the general call address (0b0000\_0000).

### I<sup>2</sup>C Device ID

This device does not support the I<sup>2</sup>C Device ID feature.

### I<sup>2</sup>C Communication Speed

This device is compatible with all four communication speed ranges as defined by the Revision 3.0 I<sup>2</sup>C specification:

- 0Hz to 100kHz (Standard Mode)
- 0Hz to 400kHz (Fast Mode)
- 0Hz to 1MHz (Fast-Mode Plus)
- 0Hz to 3.4MHz (High-Speed Mode)

Operating in standard mode, fast mode, and fast-mode plus does not require any special protocols. The main consideration when changing bus speed through this range is the combination of the bus capacitance and pullup resistors. Larger values of bus capacitance and pullup resistance increase the time constant ( $C \times R$ ), slowing bus operation. Therefore, when increasing bus speeds, the pullup resistance must be decreased to maintain a reasonable time constant. Refer to the *Pullup Resistor Sizing* section of the *I<sup>2</sup>C Bus Specification and User Manual* (available for free on the internet) for detailed guidance on the pullup resistor selection. In general for bus capacitances of 200pF, a 100kHz bus needs 5.6k $\Omega$  pullup resistors, a 400kHz bus needs about 1.5k $\Omega$  pullup resistors, and a 1MHz bus needs 680 $\Omega$  pullup resistors. Remember that, while the open-drain bus is low, the pullup resistor is dissipating power, and lower value pullup resistors dissipate more power ( $V^2/R$ ).

Operating in high-speed mode requires some special considerations. For a full list of considerations, refer to the publicly available I<sup>2</sup>C bus specification and user manual. Major considerations with respect to this part are:

- The I<sup>2</sup>C bus master uses current source pullups to shorten the signal rise.
- The I<sup>2</sup>C slave must use a different set of input filters on its SDA and SCL lines to accommodate for the higher bus.
- The communication protocols need to utilize the high-speed master code.

At power-up and after each stop condition, the bus input filters are set for standard mode, fast mode, and fast-mode plus (i.e., 0Hz to 1MHz). To switch the input filters for high-speed mode, use the high-speed master code protocols that are described in the [I<sup>2</sup>C Communication Protocols](#) section.

### I<sup>2</sup>C Communication Protocols

Both writing to and reading from registers are supported as described in the following subsections.

#### Writing to a Single Register

Figure 31 shows the protocol for the I<sup>2</sup>C master device to write one byte of data to this device. This protocol is the same as the SMBus specification's write byte protocol.

The write byte protocol is as follows:

1. The master sends a start command (S).
2. The master sends the 7-bit slave address followed by a write bit (R/W = 0).
3. The addressed slave asserts an acknowledge (A) by pulling SDA low.
4. The master sends an 8-bit register pointer.
5. The slave acknowledges the register pointer.
6. The master sends a data byte.
7. The slave updates with the new data.
8. The slave acknowledges or not acknowledges the data byte. The next rising edge on SDA loads the data byte into its target register and the data becomes active.
9. The master sends a stop condition (P) or a repeated start condition (Sr). Issuing a P ensures that the bus input filters are set for 1MHz or slower operation. Issuing an Sr leaves the bus input filters in their current state.

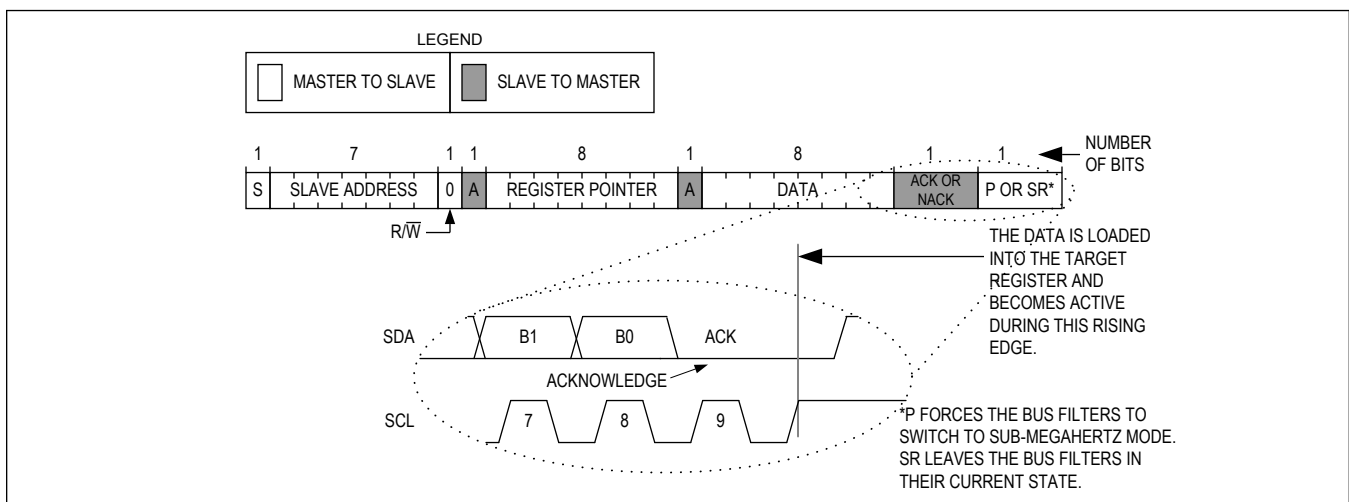

Figure 31. Writing to a Single Register with the Write Byte Protocol

**Writing Multiple Bytes to Sequential Registers**

Figure 32 shows the protocol for writing to sequential registers. This protocol is similar to the write byte protocol, except the master continues to write after it receives the first byte of data. When the master is done writing, it issues a stop or repeated start.

The writing to sequential registers protocol is as follows:

1. The master sends a start command (S).
2. The master sends the 7-bit slave address followed by a write bit (R/W = 0).
3. The addressed slave asserts an acknowledge (A) by pulling SDA low.
4. The master sends an 8-bit register pointer.
5. The slave acknowledges the register pointer.
6. The master sends a data byte.
7. The slave acknowledges the data byte. The next rising edge on SDA loads the data byte into its target register and the data becomes active.
8. Steps 6 to 7 are repeated as many times as the master requires.
9. During the last acknowledge related clock pulse, the master can issue an acknowledge or a not acknowledge.
10. The master sends a stop condition (P) or a repeated start condition (Sr). Issuing a P ensures that the bus input filters are set for 1MHz or slower operation. Issuing an Sr leaves the bus input filters in their current state.

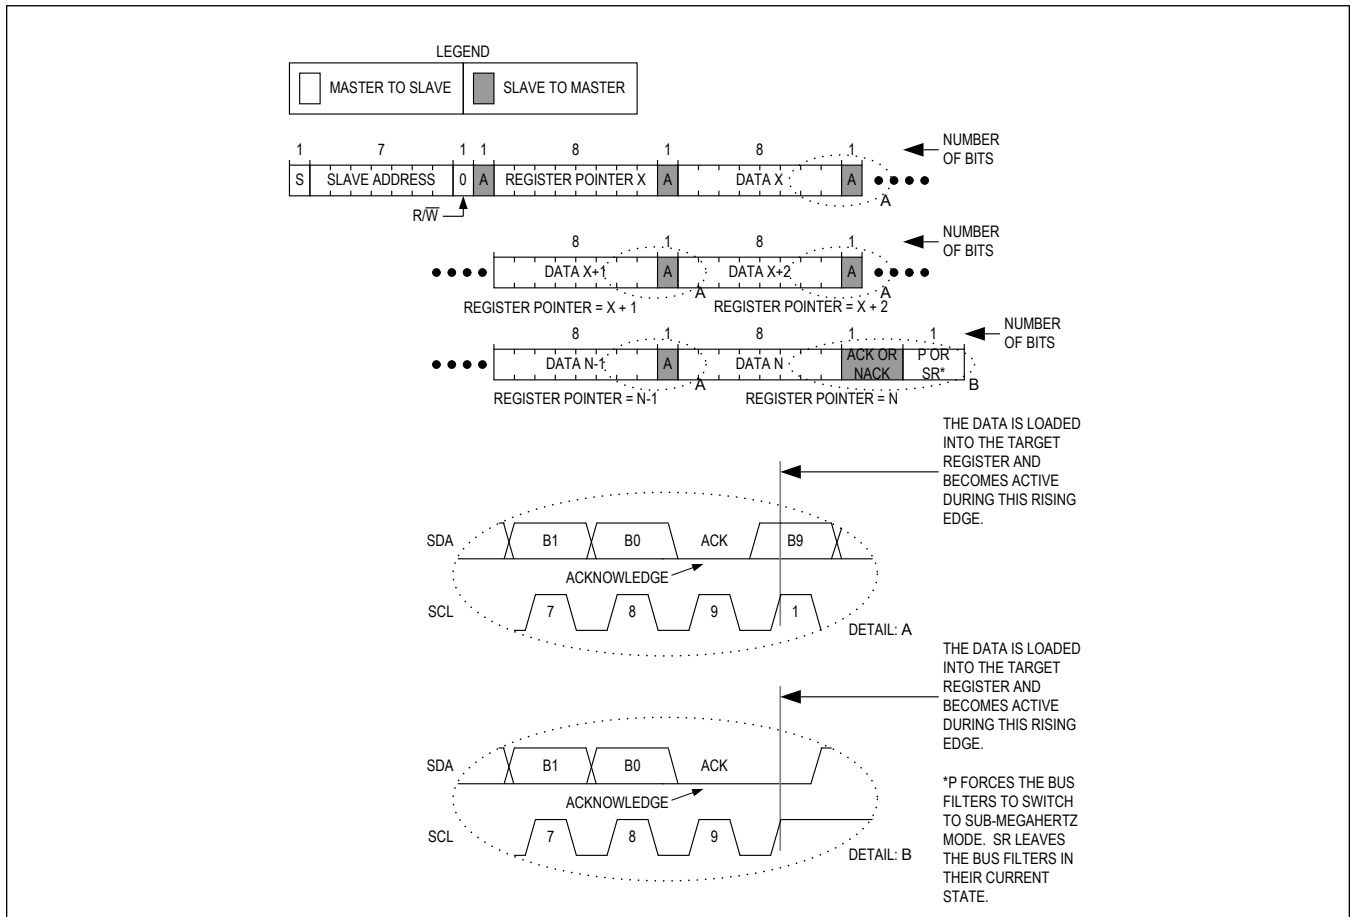

Figure 32. Writing to Sequential Registers X to N

### Reading from a Single Register

Figure 33 shows the protocol for the I<sup>2</sup>C master device to read one byte of data. This protocol is the same as the SMBus specification's read byte protocol.

The read byte protocol is as follows:

1. The master sends a start command (S).
2. The master sends the 7-bit slave address followed by a write bit ( $R/\overline{W} = 0$ ).
3. The addressed slave asserts an acknowledge (A) by pulling SDA low.
4. The master sends an 8-bit register pointer.
5. The slave acknowledges the register pointer.
6. The master sends a repeated start command (Sr).
7. The master sends the 7-bit slave address followed by a read bit ( $R/\overline{W} = 1$ ).
8. The addressed slave asserts an acknowledge by pulling SDA low.
9. The addressed slave places 8-bits of data on the bus from the location specified by the register pointer.
10. The master issues a not acknowledge (nA).
11. The master sends a stop condition (P) or a repeated start condition (Sr). Issuing a P ensures that the bus input filters are set for 1MHz or slower operation. Issuing an Sr leaves the bus input filters in their current state.

Note that when this device receives a stop, the register pointer is not modified. Therefore, if the master re-reads the same register, it can immediately send another read command, omitting the command to send a register pointer.

Figure 33. Reading from a Single Register with the Read Byte Protocol

### Reading from Sequential Registers

Figure 34 shows the protocol for reading from sequential registers. This protocol is similar to the read byte protocol except the master issues an acknowledge to signal the slave that it wants more data: when the master has all the data it requires it issues a not acknowledge (nA) and a stop (P) to end the transmission. The continuous read from sequential registers protocol is as follows:

1. The master sends a start command (S).
2. The master sends the 7-bit slave address followed by a write bit ( $R/W = 0$ ).
3. The addressed slave asserts an acknowledge (A) by pulling SDA low.
4. The master sends an 8-bit register pointer.
5. The slave acknowledges the register pointer.
6. The master sends a repeated start command (Sr).
7. The master sends the 7-bit slave address followed by a read bit ( $R/W = 1$ ).
8. The addressed slave asserts an acknowledge by pulling SDA low.
9. The addressed slave places 8-bits of data on the bus from the location specified by the register pointer.
10. The master issues an acknowledge (A) signaling the slave that it wishes to receive more data.
11. Steps 9 to 10 are repeated as many times as the master requires. Following the last byte of data, the master must issue a not acknowledge (nA) to signal that it wishes to stop receiving data.
12. The master sends a stop condition (P) or a repeated start condition (Sr). Issuing a stop (P) ensures that the bus input filters are set for 1MHz or slower operation. Issuing an Sr leaves the bus input filters in their current state.

Note that when this device receives a stop it does not modify its register pointer. Therefore, if the master re-reads the same register, it can immediately send another read command, omitting the command to send a register pointer.

Figure 34. Reading Continuously from Sequential Registers X to N

**Engaging HS-Mode for Operation up to 3.4MHz**

Figure 35 shows the protocol for engaging HS-mode operation. HS-mode operation allows for a bus operating speed up to 3.4MHz. The engaging HS-mode protocol is as follows:

1. Begin the protocol while operating at a bus speed of 1MHz or lower.
2. The master sends a start command (S).
3. The master sends the 8-bit master code of 0b0000 1XXX where 0bXXX are don't care bits.
4. The addressed slave issues a not acknowledge (nA).
5. The master may now increase its bus speed up to 3.4MHz and issue any read/write operation.

The master can continue to issue high-speed read/write operations until a stop (P) is issued. To continue operations in high-speed mode, use repeated start (Sr)

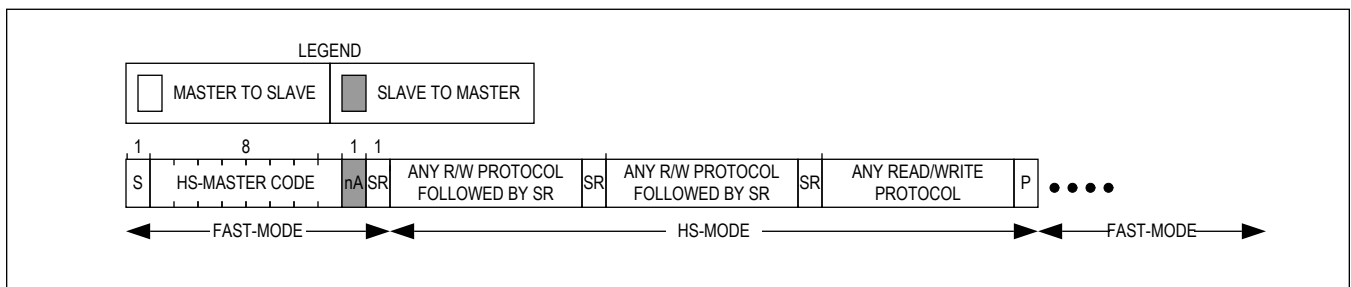

Figure 35. Engaging HS Mode

Access Type	Write, Read	Write, Read	Write, Read	Write, Read	Write, Read	Write, Read	Write, Read	

BITFIELD	BITS	DESCRIPTION	DECODE
PU_DIS	7	nEN Internal Pullup Resistor	0 = Strong internal nEN pullup (200kΩ) 1 = Weak internal nEN pullup (10MΩ)

BITFIELD	BITS	DESCRIPTION	DECODE
T_MRST	6	Sets the Manual Reset Time ( $t_{MRST}$ )	0 = 8s 1 = 3.3s
SBIA_LPM	5	Main Bias Low-Power Mode Software Request	0 = Main bias requested to be in normal-power mode by software. 1 = Main bias request to be in low-power mode by software.
SBIA_EN	4	Main Bias Enable Software Request	0 = Main bias not enabled by software. Note that the main bias can be enabled by the on/off controller. 1 = Main bias force enabled by software.
nEN_MODE	3	nEN Input (ON-KEY) Default Configuration Mode	0 = Push-button mode 1 = Slide-switch mode
DBEN_nEN	2	Debounce Timer Enable for the nEN Pin	0 = 500 $\mu$ s Debounce 1 = 30ms Debounce
SFT_CTRL	1:0	Software Reset Functions  Note that the SFT_CRST and SFT_OFF commands initiate the power-down sequence flow as described in the data sheet. This power-down sequence flow has delay elements that add up to 205.24ms (60ms delay + 10.24ms nRST assert delay + 4x2.56ms power-down slot delays + 125ms output discharge delay). If issuing the SFT_CRST and/or SFT_OFF functions in software, wait for more than 300ms before trying to issue any additional commands through I <sup>2</sup> C.	0b00 = No action 0b01 = Software cold reset (SFT_CRST). The device powers down, resets, and then powers up again. 0b10 = Software off (SFT_OFF). The device powers down, resets, and then remains off and waiting for a wake-up event. 0b11 = Factory-ship mode enter (FSM). The IC powers down, configuration registers reset, and the internal BATT to SYS switch opens. The device remains this way until a factory-ship mode exit event occurs.

BITFIELD	BITS	DESCRIPTION	DECODE
CHG_CV_JEITA	7:2	Sets the modified $V_{FAST-CHG-JEITA}$ for when the battery is either cool or warm as defined by the $V_{COOL}$ and $V_{WARM}$ temperature thresholds. This register is a don't care if the battery temperature is normal.  This 6-bit configuration is a linear transfer function that starts at 3.6V and ends at 4.6V, with 25mV increments.  Program $V_{SYS\_REG}$ to at least 200mV above the higher of $V_{FAST-CHG}$ and $V_{FAST-CHG-JEITA}$ .	0x0 = 3.600V 0x1 = 3.625V 0x2 = 3.650V ... 0x27 = 4.575V 0x28 to 0x3F = 4.600V
RSVD	1:0	Reserved. Unutilized bit. Write to 0. Reads are don't care.

Field	IMON_DISCHG_SCALE[3:0]				MUX_SEL[3:0]			
Reset	0xF				0x0			
Access Type	Write, Read				Write, Read			

BITFIELD	BITS	DESCRIPTION	DECODE
IMON_DISCHG_SCALE	7:4	Selects the battery discharge current full-scale current value.	0x0 = 8.2mA 0x1 = 40.5mA 0x2 = 72.3mA 0x3 = 103.4mA 0x4 = 134.1mA 0x5 = 164.1mA 0x6 = 193.7mA 0x7 = 222.7mA 0x8 = 251.2mA 0x9 = 279.3mA 0xA to 0xF = 300.0mA
MUX_SEL	3:0	Selects the analog channel to connect to AMUX  Note that the multiplexer consumes current unless it is in the 0b0000 state. When measurements are not needed, make sure to configure MUX_SEL[3:0] = 0b0000. Also note that for AMUX to operate, the on/off controller must be in the resource-on state.	0b0000 = Multiplexer is disabled and AMUX is high-impedance. 0b0001 = CHGIN voltage monitor. 0b0010 = Reserved 0b0011 = BATT voltage monitor. 0b0100 = BATT charge current monitor. Valid only while battery charging is happening (CHG = 1). 0b0101 = BATT discharge current monitor normal measurement. 0b0110 = BATT discharge current monitor nulling measurement. 0b0111 = THM voltage monitor. 0b1000 = TBIAS voltage monitor. 0b1001 = AGND voltage monitor (through 100Ω pulldown resistor). 0b1010 to 0b1111 = SYS voltage monitor.
