

# MP86935-A

## 60A, Intelli-Phase™ Solution with Integrated HS-FETs and LS-FETs and Driver TLGA-35 (3mmx6mm) Package

### DESCRIPTION

The MP86935-A is a monolithic half-bridge driver with built-in internal power MOSFETs and gate drivers. It achieves 60A of continuous output current across a wide input supply range.

The device can drive up to 60A per phase. The integrated drivers and MOSFETs result in high efficiency due to an optimal dead time and reduced parasitic inductance. The device operates from 100kHz to 3MHz.

The MP86935-A offers many features to simplify system design, and works with controllers with a tri-state PWM signal. It also comes with an accurate current sense to monitor the inductor current, and temperature sense to report junction temperature.

MP86935-A is ideal for server applications where efficiency and small size are a premium. The device is available in a TLGA-35 (3mmx6mm) package.

### FEATURES

- Wide 3V to 12V Operating Input Range
- 60A Output Current
- Accu-Sense™ Current Sense
- Temperature Sense
- Accepts Tri-State PWM Signal
- Current-Limit Protection
- Over-Temperature Protection (OTP)
- Fault Reporting
- Available in a TLGA (3mmx6mm) Package

### APPLICATIONS

- Server Core Voltages
- Graphic Card Core Regulators
- Power Modules

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS", the MPS logo, and "Simple, Easy Solutions" are trademarks of Monolithic Power Systems, Inc. or its subsidiaries.

### PACKAGE REFERENCE

## PIN FUNCTIONS

Pin #	Name	Description
1	VTEMP/FLT	<b>Single-pin temperature sense and fault reporting.</b> If a fault occurs, this pin is pulled up to 3.3V.
2–12, 32, 33	SW	<b>Phase node.</b>
13	VDRV	<b>Driver voltage.</b> Connect VDRV to a 3.3V supply and decouple it with a 1µF to 4.7µF ceramic capacitor.
14–20, 34	PGND	<b>Power ground.</b>
21–24, 31, 35	VIN	<b>Supply voltage.</b> Place a capacitor (C <sub>IN</sub> ) close to the device to support the switching current and reduce voltage spikes at the input.
25	PWM	<b>Pulse-width modulation input.</b> Float the PWM pin or drive it to a middle-state to put SW in a high impedance state.
26	SYNC	<b>Diode emulation mode and standby mode selection.</b> Float the SYNC pin or drive SYNC to a middle-state to enter standby mode. Pull SYNC high for continuous conduction mode (CCM). Pull SYNC low to enable diode emulation mode.
27	CS	<b>Current-sense output.</b> Use an external resistor to adjust the voltage so that it is proportional to the inductor current.
28	AGND	<b>Analog ground.</b>
29	VDD	<b>Internal circuitry voltage.</b> Connect VDD to VDRV via a 2.2Ω resistor. Decouple VDD with a 1µF capacitor connected to AGND. Connect AGND and PGND at the VDD capacitor.
30	BST	<b>Bootstrap.</b> BST requires a 0.1µF to 1µF capacitor to drive the power switch's gate above the supply voltage. Connect the capacitor between the SW and BST pins to form a floating supply across the power switch driver.

**ABSOLUTE MAXIMUM RATINGS** <sup>(1)</sup>

V <sub>IN</sub> to PGND.....	-0.3V to +16V
V <sub>IN</sub> to V <sub>SW</sub> .....	-0.3V to +16V
V <sub>IN</sub> to V <sub>SW</sub> (10ns).....	22V
V <sub>SW</sub> to PGND.....	-0.3V to +14V
V <sub>SW</sub> to PGND (25ns).....	-10V to +20V
V <sub>BST</sub> .....	V <sub>SW</sub> + 4V
V <sub>DD</sub> , V <sub>DRV</sub> .....	-0.3V to +4V
All other pins.....	-0.3V to V <sub>DD</sub> + 0.3V
Instantaneous current.....	95A
Junction temperature.....	150°C
Lead temperature.....	260°C
Storage temperature.....	-65°C to +150°C

**ESD Ratings**

Human body model (HBM).....	±2kV
Charged device model (CDM).....	±1.5kV

**Recommended Operating Conditions** <sup>(2)</sup>

Supply voltage (V <sub>IN</sub> ).....	3V to 12V
Driver voltage (V <sub>DRV</sub> ).....	3.0V to 3.6V
Logic voltage (V <sub>DD</sub> ).....	3.0V to 3.6V
Operating junction temp (T <sub>J</sub> ).....	-40°C to +125°C

<b>Thermal Resistance</b> <sup>(3)</sup>	<b>θ<sub>JB</sub></b>	<b>θ<sub>JC_TOP</sub></b>
TLGA-35 (3mmx6mm).....	2.2.....	8.0....°C/W

**Notes:**

- 1) Exceeding these ratings may damage the device.
- 2) The device is not guaranteed to function outside of its operating conditions.
- 3) θ<sub>JB</sub>: Thermal resistance from the junction to the board around the PGND soldering point.  
θ<sub>JC\_TOP</sub>: Thermal resistance from the junction to the top of the package.

## ELECTRICAL CHARACTERISTICS

$V_{IN} = 6V$ ,  $V_{DRV} = V_{DD} = SYNC = 3.3V$ ,  $T_A = 25^\circ C$  for typical values,  $T_J = -40^\circ C$  to  $+125^\circ C$  for maximum and minimum values, unless otherwise noted.

Parameter	Symbol	Condition	Min	Typ	Max	Units
I <sub>IN</sub> shutdown	I <sub>IN_OFF</sub>	SYNC = Hi-Z		90	180	μA
V <sub>IN</sub> under-voltage lockout threshold rising				2.5	2.9	V
V <sub>IN</sub> under-voltage lockout threshold hysteresis				450		mV
I <sub>VDRV</sub> quiescent current		PWM = low			400	μA
I <sub>VDD</sub> quiescent current		PWM = low		3		mA

## OPERATION

The MP86935-A is a 60A, monolithic half-bridge driver with MOSFETs. It is well-suited for multi-phase buck regulators. An external 3.3V is required to supply both VDD and VDRV. When the VIN and VDD signals are sufficiently high, operation begins.

### PWM

The PWM input pin is capable of tri-state input. If the PWM input signal is within the tri-state threshold window for about 50ns ( $t_{HL}$  or  $t_{LT}$ ), the high-side MOSFET (HS-FET) turns off immediately. The low-side MOSFET (LS-FET) enters diode emulation mode, and stays on until zero-current detection (ZCD).

The tri-state PWM input is enabled by forcing a middle-voltage PWM signal, or by floating the PWM input. The internal current source charges the signal to a middle voltage. See the PWM Timing Diagram on page 6 to define the propagation delay from PWM to the SW node.

### Standby Mode

When the SYNC pin is floating or forced to a middle-state voltage for 2 $\mu$ s, the MP86935-A enters standby mode. While in standby mode, the MP86935-A shuts down, and both the CS and VTEMP/FLT outputs are disabled. The fault (VTEMP/FLT) latch is not be reset by entering standby mode.

### Diode Emulation Mode

When PWM is low or in tri-state input in diode emulation mode, the LS-FET turns on when the inductor current is positive. The LS-FET turns off if the inductor current reaches 0A or becomes negative. There are three ways to enable diode emulation mode, listed below:

- Pull the SYNC pin low.
- Drive the PWM pin to a middle-state.
- Float the PWM pin.

### Current Sense (CS)

CS is a bidirectional current source that is proportional to the inductor current. The current-sense gain is 8 $\mu$ A/A. If required, a resistor can be used to configure the voltage gain proportional to the inductor current.

The CS output has two states (see Table 1). In standby mode, the CS circuit is disabled. It takes the device 40 $\mu$ s to exit standby mode and enter active mode.

**Table 1: CS Output States**

PWM	SYNC	CS
PWM	High	Active
PWM	Low	Active
x	Hi-Z (or middle)	Standby

To obtain an accurate CS output up to +480 $\mu$ A/-240 $\mu$ A (e.g. +60A/-30A), the CS pin's voltage must be between 0.7V and 2.1V. Generally, there is a resistor ( $R_{CS}$ ) connected from the CS pin to an external voltage that is capable of sinking small currents. This provides a sufficient voltage level to meet the required operating voltage range.

Choose a value for  $R_{CS}$  to determine a proper reference voltage ( $V_{CM}$ ). The relationship between  $R_{CS}$  and  $V_{CM}$  can be calculated with Equation (1):

$$0.7V < I_{CS} \times R_{CS} + V_{CM} < 2.1V \quad (1)$$

Where  $V_{CM}$  is a reference voltage connected to  $R_{CS}$ , and  $I_{CS}$  can be estimated with Equation (2):

$$I_{CS} = I_L \times G_{CS} \quad (2)$$

The Intelli-Phase's™ current-sense output can be used by the controller to accurately monitor the output current. The cycle-by-cycle current information from the CS pin can be used for phase current balancing, over-current protection, and active voltage positioning (output voltage droop).

### Positive and Negative Inductor Current limit

If an over-current (OC) condition is detected on the HS-FET, the HS-FET turns off for that PWM cycle. If the OC conditions lasts four consecutive cycles, the HS-FET latches off, VTEMP/FLT is pulled up to VDD, and the LS-FET turns on, and stays on until ZCD. To release the latch and restart the device, power must be cycled on VIN or VDD.

If the LS-FET detects a -30A current, the part turns off the LS-FET for 200ns to limit the

negative current. The LS-FET’s negative current limit does not trigger a fault report.

**Temperature-Sense Output with Fault Indication (VTEMP/FLT)**

The VTEMP/FLT pin can sense the junction temperature or indicate if certain faults have occurred.

**Junction Temperature Sense**

When VDD exceeds its under-voltage lockout (UVLO) threshold and the part is in active mode, the VTEMP/FLT pin has an output voltage that is proportional to the junction temperature. The gain is 10mV/°C, and it has a -100mV offset at 25°C. For example, the voltage is 0V when  $T_J < 10^\circ\text{C}$ , 0.15V when  $T_J = 25^\circ\text{C}$ , and 0.9V when  $T_J = 100^\circ\text{C}$ .

**Fault Indication**

If any fault occurs, VTEMP/FLT is typically pulled up to 3.3V (or a 3.0V minimum) to report the fault event, regardless of the temperature. After the fault occurs for 200ns, the PWM impedance changes according to the fault type. Table 2 lists how the PWM status changes for each fault type.

**Table 2: PWM Resistance if a Fault Occurs**

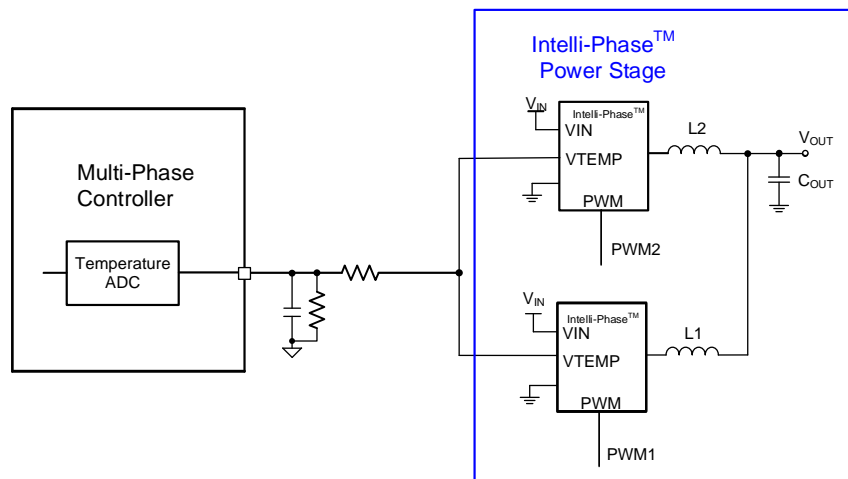

Fault Type	PWM
Current-limit protection	10kΩ to AGND
Over-temperature protection	20kΩ to AGND
SW-to-PGND short protection	1kΩ to VDD

The three fault events are described below:

1. Over-current limit: The current limit fault condition must remain for eight consecutive cycles to trigger this fault. If this fault occurs, the part latches off to turn off the HS-FET. The LS-FET turns on and stays on until the current reaches 0A. The PWM pin is pulled to GND through a 10kΩ resistor to indicate this fault type.
2. Over-temperature fault when  $T_J > 160^\circ\text{C}$ : If an over-temperature fault occurs, the part latches off, and the HS-FET turns off. The LS-FET turns on and stays on until the current reaches 0A. The PWM is pulled to GND through a 20kΩ resistor to indicate this fault type.
3. SW-to-PGND short: If a short fault occurs, the part latches off to turn off the HS-FET. The PWM pin is pulled high (1kΩ to VDD) to indicate the fault type.

The fault latch is not be reset by entering standby mode. The fault latch can be released by cycling power on VIN or VDD.

For multi-phase operation, connect the VTEMP/FLT pins of each Intelli-Phase™ together (see Figure 2).

**Figure 2: Multi-Phase Temperature Sense Utilization**

## APPLICATION INFORMATION

### PCB Layout Guidelines

PCB layout is critical for stable operation. For the best results, refer to Figure 3 and follow the guidelines below:

1. Place the input MLCC capacitors as close to the VIN and PGND pins as possible.
2. Place the major MLCC capacitors on the same layer as the MP86935-A.
3. Place as many VIN and PGND vias underneath the package as possible, as well as between the VIN or PGND long pads.
4. Place a VIN copper plane on the second inner layer to form the PCB stack as positive/negative/positive to reduce the parasitic impedance from the input MLCC capacitor.
5. Ensure that the inner layer copper planes cover the VIN vias that are beneath the package and input MLCC capacitors.
6. Place the BST capacitor and VDRV capacitor as close to the device's pins as possible, using trace paths at least 20mils wide.
7. Avoid using a via for the BST driving path. It is recommended to use a 0.1µF to 1µF bootstrap capacitor.
8. Place the VDD decoupling capacitor close to the device.
9. Connect AGND and PGND at the VDD capacitor's ground connection.
10. Keep the CS signal trace away from high-current paths, such as SW and PWM.

**Figure 3: Recommended PCB Layout (Placement and Top Layer)**

Input Capacitor: 0603 Package (Top Side and Bottom Side) and 0402 Package (Top Side)
