

Agilent HCPL-3180

2.0 Amp Output Current

High Speed Gate Drive

Optocoupler

Data Sheet

Functional Diagram

Description

This family of devices consists of a GaAsP LED. The LED is optically coupled to an integrated circuit with a power stage. These optocouplers are ideally suited for

high frequency driving of power IGBTs and MOSFETs used in Plasma Display Panels, high performance DC/DC converters, and motor control inverter applications.

Features

- 2.0 A minimum peak output current
- 250 kHz maximum switching speed
- High speed response:
200 ns maximum propagation delay over temperature range
- 10 kV/ μ s minimum Common Mode Rejection (CMR) at $V_{CM} = 1500$ V
- Under Voltage Lock-Out protection (UVLO) with hysteresis
- Wide operating temperature range: -40°C to 100°C
- Wide V_{CC} operating range: 10 V to 20 V
- 20 ns typical pulse width distortion
- Safety approvals:
 - UL approval, 3750 V_{rms} for 1 minute
 - CSA approval
 - IEC/EN/DIN EN 60747-5-2 approval

Applications

- Plasma Display Panel (PDP)
- Distributed Power Architecture (DPA)
- Switch Mode Rectifier (SMR)
- High performance DC/DC converter
- High performance Switching Power Supply (SPS)
- High performance Uninterruptible Power Supply (UPS)
- Isolated IGBT/Power MOSFET gate drive

A 0.1 μ F bypass capacitor must be connected between pins V_{CC} and Ground.

CAUTION: It is advised that normal static precautions be taken in handling and assembly of this component to prevent damage and/or degradation, which may be induced by ESD.

Ordering Information

Specify part number followed by option number (if desired).

Example:

HCPL-3180-XXXX

- No option = Standard DIP package, 50 per tube.
- 300 = Gull Wing Surface Mount Option, 50 per tube.
- 500 = Tape and Reel Packaging Option, 1000 per reel.
- 060 = IEC/EN/DIN EN 60747-5-2, $V_{IORM} = 630 V_{PEAK}$.
- XXXE = Lead Free Option.

Notes:

- Derate linearly above +70°C free air temperature at a rate of 0.3 mA/°C.
- Maximum pulse width = 10 μs , maximum duty cycle = 0.2%. This value is intended to allow for component tolerances for designs with IO peak minimum = 2.0 A. See Application section for additional details on limiting IOL peak.
- Derate linearly above +70°C, free air temperature at the rate of 4.8 mW/°C.
- Derate linearly above +70°C, free air temperature at the rate of 5.4 mW/°C. The maximum LED junction temperature should not exceed +125°C.
- Maximum pulse width = 50 μs , maximum duty cycle = 0.5%.
- In this test, V_{OH} is measured with a dc load current. When driving capacitive load V_{OH} will approach V_{CC} as I_{OH} approaches zero amps.
- Maximum pulse width = 1 ms, maximum duty cycle = 20%.
- In accordance with UL 1577, each optocoupler is proof tested by applying an insulation test voltage > 4500 V_{rms} for 1 second (leakage detection current limit $I_{I-O} < 5 \mu\text{A}$).
- Device considered a two-terminal device: pins on input side shorted together and pins on output side shorted together.
- PWD is defined as $|t_{PHL} - t_{PLH}|$ for any given device.
- Pin 1 and 4 need to be connected to LED common.
- Common mode transient immunity in the high state is the maximum tolerable dV_{CM}/dt of the common mode pulse V_{CM} to assure that the output will remain in the high state (i.e. $V_O > 10.0 \text{ V}$).
- Common mode transient immunity in a low state is the maximum tolerable dV_{CM}/dt of the common mode pulse, V_{CM} , to assure that the output will remain in a low state (i.e. $V_O < 1.0 \text{ V}$).
- t_{PHL} propagation delay is measured from the 50% level on the falling edge of the input pulse to the 50% level of the falling edge of the V_O signal.
 t_{PLH} propagation delay is measured from the 50% level on the rising edge of the input pulse to the 50% level of the rising edge of the V_O signal.
- The difference between t_{PHL} and t_{PLH} between any two HCPL-3180 parts under same test conditions.

Applications Information Eliminating Negative IGBT Gate Drive

To keep the IGBT firmly off, the HCPL-3180 has a very low maximum V_{OL} specification of 0.4 V. The HCPL-3180 realizes the very low V_{OL} by using a DMOS transistor with 1 Ω (typical) on resistance in its pull down circuit. When the HCPL-3180 is in the low state, the IGBT gate is shorted to the emitter

by $R_g + 1 \Omega$. Minimizing R_g and the lead inductance from the HCPL-3180 to the IGBT gate and emitter (possibly by mounting HCPL-3180 on a small PC board directly above the IGBT) can eliminate the need for negative IGBT gate drive in many applications as shown in Figure 25. Care should be taken with such a PC board design to avoid routing the IGBT collector or

emitter traces close to the HCPL-3180 input as this can result in unwanted coupling of transient signals into the input of HCPL-3180 and degrade performance.

(If the IGBT drain must be routed near the HCPL-3180 input, then the LED should be reverse biased when in the off state to prevent the transient signals coupled from the IGBT drain from turning on the HCPL-3180.)

Figure 25. Recommended LED drive and application circuit for HCPL-3180.

Selecting the Gate Resistor (R_g) for HCPL-3180

Step 1: Calculate R_g minimum from the I_{OL} peak specification. The IGBT and R_g in Figure 25 can be analyzed as a simple RC circuit with a voltage supplied by the HCPL-3180.

$$\begin{aligned} R_g &\geq \frac{V_{CC} - V_{OL}}{I_{OLPEAK}} \\ &= \frac{20 - 3}{2} \\ &= 8.5 \Omega \end{aligned}$$

The V_{OL} value of 3 V in the previous equation is the V_{OL} at the peak current of 2 A. (See Figure 6.)

Step 2: Check the HCPL-3180 power dissipation and increase R_g if necessary. The HCPL-3180 total power dissipation (P_T) is equal to the sum of the emitter power (P_E) and the output power (P_O).

$$P_T = P_E + P_O$$

$$P_E = I_F * V_F * \text{Duty Cycle}$$

$$\begin{aligned} P_O &= P_{O(BIAS)} + P_{O(SWITCHING)} \\ &= I_{CC} * V_{CC} + E_{SW} (R_g; Q_g) * f \end{aligned}$$

For the circuit in Figure 25 with I_F (worst case) = 16 mA, $R_g = 10 \Omega$, Max Duty Cycle = 80%, $Q_g = 100 \text{ nC}$, $f = 200 \text{ kHz}$ and $T_{AMAX} = +75^\circ\text{C}$:

$$P_E = 16 \text{ mA} * 1.8 \text{ V} * 0.8 = 23 \text{ mW}$$

$$\begin{aligned} P_O &= 4.5 \text{ mA} * 20 \text{ V} + 0.85 \mu * 200 \text{ kHz} \\ &= 260 \text{ mW} \geq 226 \text{ mW} (P_{O(MAX)} @ 75^\circ\text{C} = 250 \text{ mW} (5^\circ\text{C} * 4.8 \text{ mW}/^\circ\text{C})) \end{aligned}$$

The value of 4.5 mA for I_{CC} in the previous equation was obtained by derating the I_{CC} max of 6 mA to I_{CC} max at $+75^\circ\text{C}$. Since P_O for this case is greater than the $P_{O(MAX)}$, R_g must be increased to reduce the HCPL-3180 power dissipation.

$$\begin{aligned} P_{O(SWITCHING MAX)} &= P_{O(MAX)} - P_{O(BIAS)} \\ &= 226 \text{ mW} - 90 \text{ mW} \\ &= 136 \text{ mW} \end{aligned}$$

$$\begin{aligned} E_{SW(MAX)} &= \frac{P_{O(SWITCHING MAX)}}{f} \\ &= \frac{136 \text{ mW}}{200 \text{ kHz}} \\ &= 0.68 \mu\text{W} \end{aligned}$$

For $Q_g = 100 \text{ nC}$, a value of $E_{SW} = 0.68 \mu\text{W}$ gives a $R_g = 15 \Omega$.

Figure 26. Energy dissipated in the HCPL-3180 and for each IGBT.

**Thermal Model
(Discussion applies to HCPL-3180)**

The steady state thermal model for the HCPL-3180 is shown in Figure 27. The thermal resistance values given in this model can be used to calculate the temperatures at each node for a given operating condition. As shown by the model, all heat generated

flows through θ_{CA} which raises the case temperature T_C accordingly. The value of θ_{CA} depends on the conditions of the board design and is, therefore, determined by the designer. The value of $\theta_{CA} = +83^\circ\text{C/W}$ was obtained from thermal measurements using a 2.5 x 2.5 inch PC board, with small traces (no ground plane), a

single HCPL- 3180 soldered into the center of the board and still air. The absolute maximum power dissipation derating specifications assume a θ_{CA} value of $+83^\circ\text{C/W}$. From the thermal mode in Figure 27, the LED and detector IC junction temperatures can be expressed as:

$$T_{JE} = P_E * (\theta_{LC} // \theta_{LD} + \theta_{DC}) + \theta_{CA} + P_D * \left[\frac{\theta_{LC} * \theta_{DC}}{\theta_{LC} + \theta_{DC} + \theta_{LD}} + \theta_{CA} \right] + T_A$$

$$T_{JD} = P_E * \left[\frac{\theta_{LC} * \theta_{DC}}{\theta_{LC} + \theta_{DC} + \theta_{LD}} + \theta_{CA} \right] + P_D * (\theta_{LC} // \theta_{LD} + \theta_{DC}) + \theta_{CA} + T_A$$

Figure 27. Thermal model.

$$T_{JE} = P_E * (256^\circ\text{C/W} + \theta_{CA}) + P_D * (57^\circ\text{C/W} + \theta_{CA}) + T_A$$

$$T_{JD} = P_E * (57^\circ\text{C/W} + \theta_{CA}) + P_D * (111^\circ\text{C/W} + \theta_{CA}) + T_A$$

For example, given $P_E = 45\text{ mW}$,

$P_D = 250\text{ mW}$, $T_A = +70^\circ\text{C}$ and $\theta_{CA} = +83^\circ\text{C/W}$:

$$\begin{aligned} T_{JE} &= P_E * 339^\circ\text{C/W} + P_D * 140^\circ\text{C/W} + T_A \\ &= 45\text{ mW} * 339^\circ\text{C/W} + 250\text{ mW} * 140^\circ\text{C/W} + 70^\circ\text{C} \\ &= 120^\circ\text{C} \end{aligned}$$

$$\begin{aligned} T_{JD} &= P_E * 140^\circ\text{C/W} + P_D * 194^\circ\text{C/W} + T_A \\ &= 45\text{ mW} * 140^\circ\text{C/W} + 250\text{ mW} * 194^\circ\text{C/W} + 70^\circ\text{C} \\ &= 125^\circ\text{C} \end{aligned}$$

T_{JE} and T_{JD} should be limited to $+125^\circ\text{C}$ based on the board layout and part placement (θ_{CA}) specific to the application.

LED Drive Circuit Considerations for Ultra High CMR Performance

Without a detector shield, the dominant cause of optocoupler CMR failure is capacitive coupling from the input side of the optocoupler, through the package, to the detector IC as shown in Figure 28. The HCPL-3180 improves CMR performance by using a detector IC with an optically transparent Faraday shield, which

Figure 28. Optocoupler input to output capacitance model for unshielded optocouplers.

diverts the capacitively coupled current away from the sensitive IC circuitry. However, this shield does not eliminate the capacitive coupling between the LED and optocoupler pins 5-8 as shown in Figure 29. This capacitive coupling causes perturbations in the LED current during common mode transients and becomes the major source of CMR failures for a shielded optocoupler. The main

Figure 29. Optocoupler input to output capacitance model for shielded optocouplers.

design objective of a high CMR LED drive circuit becomes keeping the LED in the proper state (on or off) during common mode transients. For example, the recommended application circuit (Figure 25), can achieve 10 kV/μs CMR while minimizing component complexity.

Techniques to keep the LED in the proper state are discussed in the next two sections.

CMR with the LED On (CMR_H)

A high CMR LED drive circuit must keep the LED on during common mode transients. This is achieved by over-driving the LED current beyond the input threshold so that it is not pulled below the threshold during a transient. A minimum LED current of 10 mA provides adequate margin over the maximum I_{FLH} of 8 mA to achieve 10 kV/μs CMR.

CMR with the LED Off (CMR_L)

A high CMR LED drive circuit must keep the LED off ($V_F \leq V_{F(OFF)}$) during common mode transients. For example, during a $-dV_{CM}/dt$ transient in Figure 30, the current flowing through C_{LEDP} also flows through the R_{SAT} and V_{SAT} of the logic gate. As long as the low state voltage developed across the logic gate is less than $V_{F(OFF)}$, the LED will remain off and no common mode failure will occur.

The open collector drive circuit, shown in Figure 31, cannot keep the LED off during a $+dV_{CM}/dt$ transient, since all the current flowing through C_{LEDN} must be supplied by the LED, and it is not recommended for applications requiring ultra high CMR_L

performance. Figure 32 is an alternative drive circuit, which like the recommended application circuit (Figure 25), does achieve ultra high CMR performance by shunting the LED in the off state.

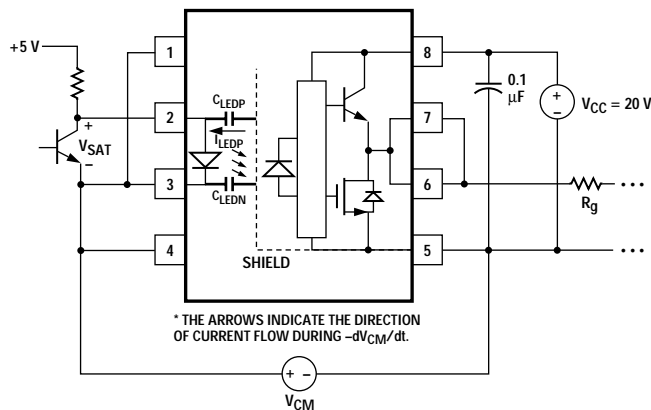

Figure 30. Equivalent circuit for Figure 25 during common mode transient.

Figure 31. Not recommended open collector drive circuit.

Figure 32. Recommended LED drive circuit for ultra-high CMR.

Under Voltage Lockout Feature

The HCPL-3180 contains an under voltage lockout (UVLO) feature that is designed to protect the IGBT under fault conditions which cause the HCPL-3180 supply voltage (equivalent to the fully charged IGBT gate voltage) to drop below a level necessary to keep the IGBT in a low resistance state. When the HCPL-3180 output is in the high state and the supply voltage drops below the HCPL-3180 V_{UVLO-} threshold (typ 7.5 V) the optocoupler output will go into the low state. When the HCPL-3180 output is in the low state and the supply voltage rises above the HCPL-3180 V_{UVLO+} threshold (typ 8.5 V) the optocoupler output will go into the high state (assume LED is “ON”).

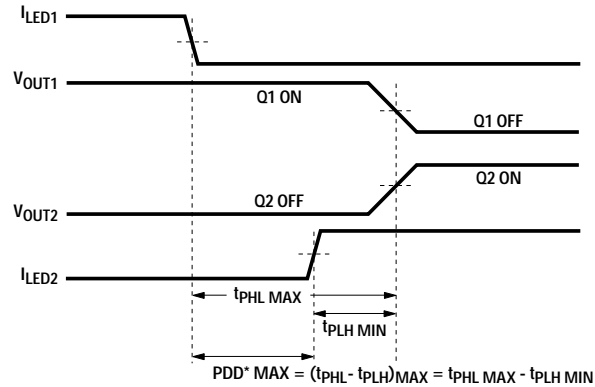

Figure 33. Under voltage lock out.

IPM Dead Time and Propagation Delay Specifications

The HCPL-3180 includes a Propagation Delay Difference (PDD) specification intended to help designers minimize “dead time” in their power inverter designs. Dead time is the time during which the high and low side power transistors are off. Any overlap in Q1 and Q2 conduction will result in large currents flowing through the power devices from the high voltage to the low-voltage motor rails.

To minimize dead time in a given design, the turn on of LED2 should be delayed (relative to the turn off of LED1) so that under worst-case conditions, transistor Q1 has just turned off when transistor Q2 turns on, as shown in Figure 34. The amount of delay necessary to achieve this condition is equal to the maximum value of the propagation delay difference specification, PDD_{MAX} , which is specified to be 90 ns over the operating temperature range of $-40^{\circ}C$ to $+100^{\circ}C$.

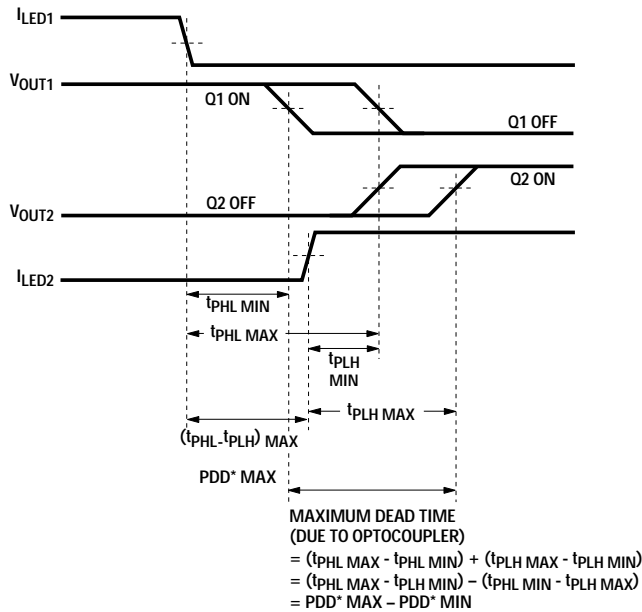

*PDD = PROPAGATION DELAY DIFFERENCE
NOTE: FOR PDD CALCULATIONS, THE PROPAGATION DELAYS ARE TAKEN AT THE SAME TEMPERATURE AND TEST CONDITIONS.

Figure 34. Minimum LED skew for zero dead time.

Delaying the LED signal by the maximum propagation delay difference ensures that the minimum dead time is zero, but it does not tell a designer what the maximum dead time will be. The maximum dead time is equivalent to the difference between the maximum

and minimum propagation delay difference specification as shown in Figure 35. The maximum dead time for the HCPL-3180 is 180 ns (= 90 ns - (-90 ns)) over the operating temperature range of -40 °C to +100 °C.

*PDD = PROPAGATION DELAY DIFFERENCE

NOTE: FOR DEAD TIME AND PDD CALCULATIONS, ALL PROPAGATION DELAYS ARE TAKEN AT THE SAME TEMPERATURE AND TEST CONDITIONS.

Figure 35. Waveforms for dead time.

Note that the propagation delays used to calculate PDD and dead time are taken at equal temperatures and test conditions since the optocouplers under consideration are typically mounted in close proximity to each other and are switching identical IGBTs.
