

## Dual and Quad Precision Micropower Single Supply Rail-to-Rail Input and Output Precision Op Amps

The ISL28276 and ISL28476 are Dual and Quad channel micropower precision operational amplifier optimized for single supply operation at 5V and can operate down to 2.4V. For equivalent performance in a single channel op-amp reference EL8176.

The ISL28276 and ISL28476 feature an Input Range Enhancement Circuit (IREC) which enables both parts to maintain CMRR performance for input voltages equal to the positive and negative supply rails. The input signal is capable of swinging 0.5V above a 5.0V supply (0.25V for a 2.4V supply) and to within 10mV from ground. The output operation is rail to rail.

The both parts draw minimal supply current while meeting excellent DC-accuracy, AC-performance, noise and output drive specifications. Offset current, voltage and current noise, slew rate, and gain-bandwidth product are all two to ten times better than other micropower op-amps with equivalent supply current ratings.

The ISL28276 and ISL28476 can be operated from one lithium cell or two Ni-Cd batteries. The input range includes both positive and negative rail.

Coming Soon ISL28476FAZ-T7	28476 FAZ	7" (1k pcs)	16 Ld QSOP	MDP0040

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

### Features

- 60 $\mu$ A supply current per channel
- 100 $\mu$ V max offset voltage
- 500pA input bias current
- 400kHz gain-bandwidth product
- 115dB PSRR and CMRR
- Single supply operation down to 2.4V
- Input is capable of swinging above V+ and within 10mV of Ground
- Rail-to-rail output
- Output sources 31mA load current
- Pb-free plus anneal available (RoHS compliant)

### Applications

- Battery- or solar-powered systems
- 4mA to 25mA current loops
- Handheld consumer products
- Medical devices
- Thermocouple amplifiers
- Photodiode pre-amps
- pH probe amplifiers

Applications Information

Introduction

The ISL28276 and ISL28476 are Dual and Quad channel CMOS rail-to-rail input, output (RRIO) micropower precision operational amplifier with an enable feature. The parts are designed to operate from single supply (2.4V to 5.0V) or dual supply ( $\pm 1.2V$  to  $\pm 2.5V$ ) while drawing only 120 $\mu A$  of supply current. The device has an input common mode range that extends 10% above the positive rail and up to 100mV below the negative supply rail. The output operation can swing within about 4mV of the supply rails with a 100k $\Omega$  load (reference Figures 29 through 32). This combination of low power and precision performance makes them suitable for solar and battery power applications.

Rail-to-Rail Input

The input common-mode voltage range of the ISL28276 and ISL28476 is from the negative supply to 10% greater than

the positive supply without introducing additional offset errors or degrading performance associated with a conventional rail-to-rail input operational amplifier. Many rail-to-rail input stages use two differential input pairs, a long-tail PNP (or PFET) and an NPN (or NFET). Severe penalties have to be paid for this circuit topology. As the input signal moves from one supply rail to another, the operational amplifier switches from one input pair to the other causing drastic changes in input offset voltage and an undesired change in magnitude and polarity of input offset current.

The ISL28276 and ISL28476 achieve input rail-to-rail operation without sacrificing important precision specifications and degrading distortion performance. The devices' input offset voltage exhibits a smooth behavior throughout the entire common-mode input range. The input bias current versus the common-mode voltage range gives us an undistorted behavior from typically 100mV below the

negative rail and 10% higher than the V+ rail (0.5V higher than V+ when V+ equals 5V).

### Input Protection

All input terminals have internal ESD protection diodes to both positive and negative supply rails, limiting the input voltage to within one diode beyond the supply rails. They have additional back-to-back diodes across the input terminals. For applications where the input differential voltage is expected to exceed 0.5V, external series resistors must be used to ensure the input currents never exceed 5mA.

### Input Bias Current Compensation

The input bias currents are decimated down to a typical of 500pA while maintaining an excellent bandwidth for a micro-power operational amplifier. Inside the ISL28276 and ISL28476 is an input bias canceling circuit. The input stage transistors are still biased with an adequate current for speed but the canceling circuit sinks most of the base current, leaving a small fraction as input bias current.

### Rail-to-Rail Output

A pair of complementary MOSFET devices are used to achieve the rail-to-rail output swing. The NMOS sinks current to swing the output in the negative direction. The PMOS sources current to swing the output in the positive direction. The output with a 100k $\Omega$  load will swing to within 3mV of the supply rails.

### Enable/Disable Feature

The ISL28276 offers an  $\overline{\text{EN}}$  pin that disables the device when pulled up to at least 2.2V. In the disabled state (output in a high impedance state), the part consumes typically 4 $\mu$ A. By disabling the part, multiple ISL28276 parts can be connected together as a MUX. The outputs are tied together in parallel and a channel can be selected by the  $\overline{\text{EN}}$  pin. The  $\overline{\text{EN}}$  pin also has an internal pull down. If left open, the  $\overline{\text{EN}}$  pin will pull to the negative rail and the device will be enabled by default.

### Proper Layout Maximizes Performance

To achieve the maximum performance of the high input impedance and low offset voltage, care should be taken in the circuit board layout. The PC board surface must remain clean and free of moisture to avoid leakage currents between adjacent traces. Surface coating of the circuit board will reduce surface moisture and provide a humidity barrier, reducing parasitic resistance on the board. When input leakage current is a concern, the use of guard rings around the amplifier inputs will further reduce leakage currents. Figure 39 shows a guard ring example for a unity gain amplifier that uses the low impedance amplifier output at the same voltage as the high impedance input to eliminate surface leakage. The guard ring does not need to be a specific width, but it should form a continuous loop around both inputs. For further reduction of leakage currents,

components can be mounted to the PC board using Teflon standoff insulators.

FIGURE 39. GUARD RING EXAMPLE FOR UNITY GAIN AMPLIFIER

### Example Application

Thermocouples are the most popular temperature-sensing device because of their low cost, interchangeability, and ability to measure a wide range of temperatures. The ISL28276 (Figure 40) is used to convert the differential thermocouple voltage into single-ended signal with 10X gain. The ISL28276's rail-to-rail input characteristic allows the thermocouple to be biased at ground and the converter to run from a single 5V supply.
