General Description

The MAX4359/MAX4360/MAX4456 low-cost video crosspoint switches are designed to reduce component count, board space, design time, and system cost. Each contains a matrix of T-switches that connect any of their four (MAX4359) or eight (MAX4360/MAX4456) video inputs to any of their buffered outputs, in any combination. Each matrix output is buffered by an internal, high-speed (250V/µs), unity-gain amplifier that is capable of driving 400Ω and 20pF at 2.6V p-p. For applications requiring increased drive capability, buffer the MAX4359/MAX4360/MAX4456 outputs with the MAX4395 quad, operational amplifier.

The MAX4456 has a digitally controlled 8x8 switch matrix and is a low-cost pin-for-pin compatible alternative to the popular MAX456. The MAX4359/MAX4360 are similar to the MAX4456, with the 8x8 switch matrix replaced by a 4x4 (MAX4359) or an 8x4 (MAX4360) switch matrix.

Three-state output capability and internal, programmable active loads make it feasible to parallel multiple devices to form larger switch arrays. The inputs and outputs are on opposite sides, and a quiet power supply or digital input line separates each channel, which reduces crosstalk to -70dB at 5MHz. For applications demanding better DC specifications, see the MAX456 8x8 video crosspoint switch.

Applications

High-Speed Signal Routing
Video Test Equipment
Video-On-Demand Systems
Security Systems

Features

♦ Eight (MAX4456) or Four (MAX4359/MAX4360) Internal Buffers
♦ 250V/µs Slew Rate
♦ Three-State Output Capability
♦ Power-Saving Disable Feature
♦ 65MHz -3dB Bandwidth
♦ Routes Any Input Channel to Any Output Channel
♦ Serial or Parallel Digital Interface
♦ Expandable for Larger Switch Matrices
♦ 80dB All-Channel Off-Isolation at 5MHz
♦ 70dB Single-Channel Crosstalk
♦ Straight-Through Pinout Simplify Layout
♦ Low-Cost Pin-Compatible Alternative to MAX456 (MAX4456)

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

- **SER/PAR**
  - Connect to VCC for serial mode; connect to GND for parallel mode.
- **V-**
  - In serial mode, WR (write) shifts data into the input register. In parallel mode, WR loads data into the 1st-rank registers. Data is latched on the rising edge.
- **LATCH**
  - If EDGE/LEVEL = VCC, data is loaded from the 1st-rank registers to the 2nd-rank registers on the rising edge of LATCH. If EDGE/LEVEL = GND, data is loaded while LATCH = GND. In addition, data is loaded during the execution of parallel-mode functions 1011 through 1110, or if LATCH = VCC during the execution of the parallel-mode “software-latch” command (1111).

Detailed Description

Output Buffers

The MAX4456 video crosspoint switch consists of 64 T-switches in an 8x8 grid (Figure 1). The eight matrix outputs are followed by eight wideband buffers optimized for driving 400Ω and 20pF loads. The MAX4359’s core is a 4x4 switch matrix with each of its outputs followed by a wideband buffer. The MAX4360 has an 8x4 matrix and four output buffers. Each buffer has an internal active load on the output that can be readily shut off through the LOAD input (off when LOAD = 0V). The shut-off is useful when two or more crosspoints are connected in parallel to create more input channels. With more input channels, only one set of buffers can be active and only one set of loads can be driven. When active, the buffer must have either 1) an internal load, 2) the internal load of another buffer in another MAX4359/MAX4360/MAX4456, or 3) an external load.

Each output can be disabled under logic control. When a buffer is disabled, its output enters a high-impedance state. In multichip parallel applications, the disable function prevents inactive outputs from loading lines driven by other devices. Disabling the inactive buffers reduces power consumption.

The outputs connect easily to MAX4395 quad, operational amplifiers when back-terminated 75Ω coaxial cable must be driven.

Figure 1. MAX4456 Functional Diagram
Power-On RESET
The MAX4359/MAX4360/MAX4456 have an internal power-on reset (POR) circuit that remains low for 5µs after power is applied. POR also remains low if the total supply voltage is less than 4V. The POR disables all buffer outputs at power-up, but the switch matrix is not preset to any initial condition. The desired switch state should be programmed before the buffer outputs are enabled.

Digital Interface
The desired switch state can be loaded in a parallel-interface mode or serial-interface mode (Table 3 and Figures 4, 5, 6). All action associated with the WR line occurs on its rising edge. The same is true for the LATCH line if EDGE/LEVEL is high. Otherwise, the second-rank registers update while LATCH is low (when EDGE/LEVEL is low). WR is logically ANDed with CE and CE (when present) to allow active-high or active-low chip enable.

6-Bit Parallel-Interface Mode (MAX4359/MAX4360)
In the MAX4359/MAX4360’s parallel-interface mode (SER/PAR = GND), the six data bits specify an output channel (A1, A0) and the input channel to which it connects (D3–D0). This data is loaded on the rising edge of WR. The input channels are selected by codes 0000 through 0111 (D3–D0) for the MAX4360, and codes 0000 through 0011 (D3–D0) for the MAX4359. Note that the MAX4359 does not use codes 0100 through 0111. The eight codes 1000 through 1111 control other functions, as listed in Table 1.

7-Bit Parallel-Interface Mode (MAX4456)
In the MAX4456’s parallel-interface mode (SER/PAR = GND), the seven data bits specify an output channel (A2, A1, A0) and the input channel to which it connects (D3–D0). This data is loaded on the rising edge of WR. The input channels are selected by codes 0000 through 0111 (D3–D0) for the MAX4456. The remaining eight codes 1000 through 1111 control other functions, as listed in Table 1.

16-Bit Serial-Interface Mode (MAX4359/MAX4360)
In serial mode (SER/PAR = VCC), all first-rank registers are loaded with data, making it unnecessary to specify an output address (A1, A0). The input data format is D3–D0, starting with OUT0 and ending with OUT3 for 16 total bits. For the MAX4360, only codes 0000 through 1010 are valid. For the MAX4359, only the codes 0000 through 0011 and codes 1000 through 1010 are valid. Code 1010 disables a buffer, while code 1001 enables it. After data is shifted into the 16-bit first-rank register, it is transferred to the second rank by LATCH (Table 2), which updates the switches.

Low-Cost 4x4, 8x4, 8x8 Video Crosspoint Switches

32-Bit Serial-Interface Mode (MAX4456)

In serial mode (SER/PAR = Vcc), all first-rank registers are loaded with data, making it unnecessary to specify an output address (A2, A1, A0). The input data format is D3–D0, starting with OUT0 and ending with OUT7 for 32 total bits. Only codes 0000 through 1010 are valid. Code 1010 disables a buffer, while code 1001 enables it. After data is shifted into the 32-bit first-rank register, it is transferred to the second rank by LATCH (Table 2), which updates the switches.

Typical Application

Figure 2 shows a typical application of the MAX4456 (PDIP) with the MAX4395 quad, operational amplifiers at the outputs to drive 75Ω loads. This application shows the MAX4456 digital-switch control interface set up in the 7-bit parallel mode. The MAX4456 uses seven data lines and two control lines (WR and LATCH). Two additional lines may be needed to control CE and LOAD when using multiple MAX4456s.

The input/output information is presented to the chip at A2, A1, A0, and D3–D0 by a parallel printer port. The data is stored in the 1st-rank registers on the rising edge of WR. When the LATCH line goes high, the switch configuration is loaded into the 2nd-rank registers, and all eight outputs enter the new configuration at the same time. Each 7-bit word updates only one output buffer at a time. If several buffers are to be updated, the data is individually loaded into the 1st-rank registers. Then, a single LATCH pulse is used to reconfigure all channels simultaneously.

The short BASIC program in Figure 3 loads programming data into the MAX4456 from any IBM PC or compatible. It uses the computer’s “LPT1” output to interface to the circuit, then automatically finds the address for LPT1 and displays a table of valid input values to be used. The program does not keep track of previous commands, but it does display the last data sent to LPT1, which is written and latched with each transmission. A similar application is possible with the MAX4359/MAX4360.

Low-Cost 4x4, 8x4, 8x8 Video Crosspoint Switches

Note 1: Connect LOAD to +5V (internal 400\(\Omega\) loads on at all outputs).
Note 2: Program any one input to connect to any one output. See Table 1 or 2 for programming codes.
Note 3: Turn on the buffer at the selected output (Table 1 or 2).
Note 4: Drive the selected input with \(V_{IN}\), and measure \(V_{OUT}\) at the -3dB frequency at the selected output.
Note 5: Program each numbered input to connect to the same numbered output (IN0 to OUT0, IN1 to OUT1, etc., for the MAX4456; also IN4 to OUT0, IN5 to OUT1, etc., for the MAX4360.) See Table 1 or 2 for programming codes.
Note 6: Turn off all output buffers (Table 1 or 2).
Note 7: Drive all inputs with \(V_{IN}\), and measure \(V_{OUT}\) at any output.
Note 8: Isolation (in dB) = 20\(\log_{10}(V_{OUT}/V_{IN})\).
Note 9: Turn on all output buffers (Table 1 or 2).
Note 10: Drive any one input with \(V_{IN}\), and measure \(V_{OUT}\) at any undriven output.
Note 11: Crosstalk (in dB) = 20\(\log_{10}(V_{OUT}/V_{IN})\).
Note 12: Drive all but one input with \(V_{IN}\), and measure \(V_{OUT}\) at the undriven output.
