### DESCRIPTION

The M48Z58/Y ZEROPOWER® RAM is an 8K x 8 non-volatile static RAM that integrates power-fail deselect circuitry and battery control logic on a single die. The monolithic chip is available in two special packages to provide a highly integrated battery backed-up memory solution.

The M48Z58/Y is a non-volatile pin and function equivalent to any JEDEC standard 8K x 8 SRAM. It also easily fits into many ROM, EPROM, and EEPROM sockets, providing the non-volatility of PROMs without any requirement for special WRITE timing or limitations on the number of WRITES that can be performed.

The 28-pin, 600mil DIP CAPHAT™ houses the M48Z58/Y silicon with a long life lithium button cell in a single package.

The 28-pin, 330mil SOIC provides sockets with gold plated contacts at both ends for direct connection to a separate SNAPHAT® housing containing the battery. The unique design allows the SNAPHAT battery package to be mounted on top of the SOIC package after the completion of the surface mount process. Insertion of the SNAPHAT housing after reflow prevents potential battery damage due to the high temperatures required for device surface-mounting. The SNAPHAT housing is keyed to prevent reverse insertion.

The SOIC and battery packages are shipped separately in plastic anti-static tubes or in Tape & Reel form.

For the 28-lead SOIC, the battery package (e.g., SNAPHAT) part number is "M4Z28-BR00SH" (see Table 16., page 18).

## OPERATING MODES

The M48Z58/Y also has its own Power-fail Detect circuit. The control circuitry constantly monitors the single 5V supply for an out of tolerance condition. When  $V_{CC}$  is out of tolerance, the circuit write protects the SRAM, providing a high degree of

data security in the midst of unpredictable system operation brought on by low  $V_{CC}$ . As  $V_{CC}$  falls below battery switchover voltage ( $V_{SO}$ ), the control circuitry connects the battery which maintains data until valid power returns.

**Table 2. Operating Modes**

Note: X =  $V_{IH}$  or  $V_{IL}$ ;  $V_{SO}$  = Battery Back-up Switchover Voltage.

Note: 1. See Table 10., page 13 for details.

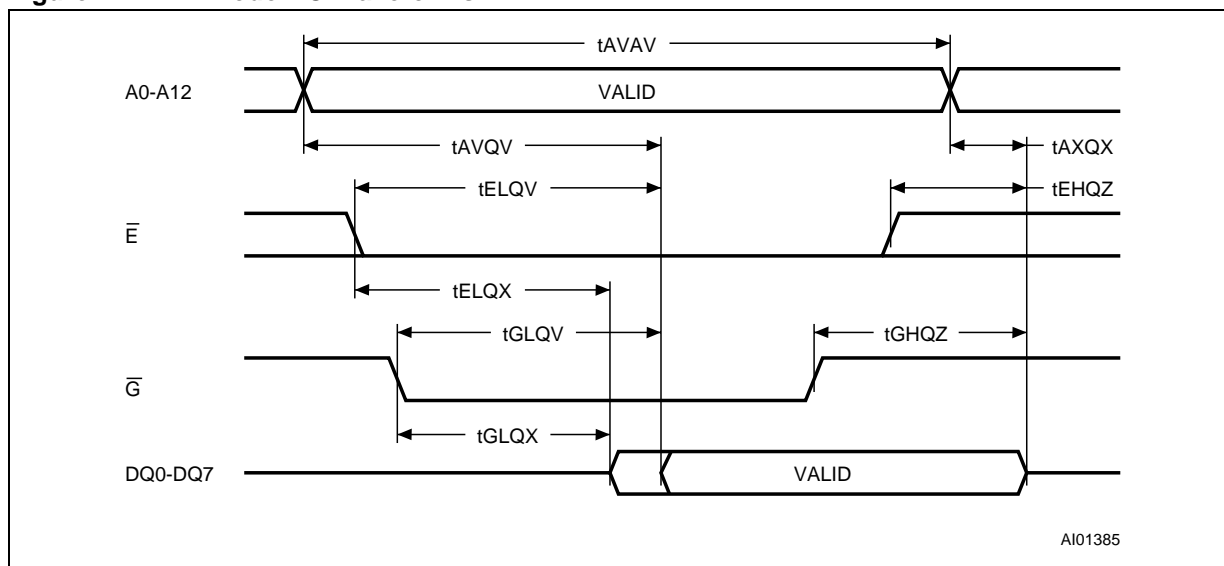

### READ Mode

The M48Z58/Y is in the READ Mode whenever  $\bar{W}$  (WRITE Enable) is high,  $\bar{E}$  (Chip Enable) is low. Thus, the unique address specified by the 13 Address Inputs defines which one of the 8,192 bytes of data is to be accessed. Valid data will be available at the Data I/O pins within Address Access time ( $t_{AVQV}$ ) after the last address input signal is stable, providing that the  $\bar{E}$  and  $\bar{G}$  access times are also satisfied. If the  $\bar{E}$  and  $\bar{G}$  access times are not met, valid data will be available after the latter

of the Chip Enable Access time ( $t_{ELQV}$ ) or Output Enable Access time ( $t_{GLQV}$ ).

The state of the eight three-state Data I/O signals is controlled by  $\bar{E}$  and  $\bar{G}$ . If the outputs are activated before  $t_{AVQV}$ , the data lines will be driven to an indeterminate state until  $t_{AVQV}$ . If the Address Inputs are changed while  $\bar{E}$  and  $\bar{G}$  remain active, output data will remain valid for Output Data Hold time ( $t_{AXQX}$ ) but will go indeterminate until the next Address Access.

**Figure 7. READ Mode AC Waveforms**

Note: WRITE Enable ( $\bar{W}$ ) = High.

2.  $C_L = 5\text{pF}$  (see Figure 11., page 11).

### WRITE Mode

The M48Z58/Y is in the WRITE Mode whenever  $\overline{W}$  and  $\overline{E}$  are low. The start of a WRITE is referenced from the latter occurring falling edge of  $\overline{W}$  or  $\overline{E}$ . A WRITE is terminated by the earlier rising edge of  $\overline{W}$  or  $\overline{E}$ . The addresses must be held valid throughout the cycle.  $\overline{E}$  or  $\overline{W}$  must return high for a minimum of  $t_{EHAX}$  from Chip Enable or  $t_{WHAX}$  from WRITE Enable prior to the initiation of another

READ or WRITE cycle. Data-in must be valid  $t_{D-VWH}$  prior to the end of WRITE and remain valid for  $t_{WHDX}$  afterward.  $\overline{G}$  should be kept high during WRITE cycles to avoid bus contention; although, if the output bus has been activated by a low on  $\overline{E}$  and  $\overline{G}$ , a low on  $\overline{W}$  will disable the outputs  $t_{WLQZ}$  after  $\overline{W}$  falls.

Note: 1. Valid for Ambient Operating Temperature:  $T_A = 0$  to  $70^\circ\text{C}$ ;  $V_{CC} = 4.75$  to  $5.5\text{V}$  or  $4.5$  to  $5.5\text{V}$  (except where noted).  
 2.  $C_L = 5\text{pF}$  (see Figure 11., page 11).  
 3. If  $\bar{E}$  goes low simultaneously with  $\bar{W}$  going low, the outputs remain in the high impedance state.

### Data Retention Mode

With valid  $V_{CC}$  applied, the M48Z58/Y operates as a conventional BYTEWIDE™ static RAM. Should the supply voltage decay, the RAM will automatically power-fail deselect, write protecting itself when  $V_{CC}$  falls within the  $V_{PFD}$  (max),  $V_{PFD}$  (min) window. All outputs become high impedance, and all inputs are treated as “Don't care.”

**Note:** A power failure during a WRITE cycle may corrupt data at the currently addressed location, but does not jeopardize the rest of the RAM's content. At voltages below  $V_{PFD}$  (min), the user can be assured the memory will be in a write protected state, provided the  $V_{CC}$  fall time is not less than  $t_f$ . The M48Z58/Y may respond to transient noise spikes on  $V_{CC}$  that reach into the deselect window during the time the device is sampling  $V_{CC}$ . Therefore, decoupling of the power supply lines is recommended.

When  $V_{CC}$  drops below  $V_{SO}$ , the control circuit switches power to the internal battery which preserves data. The internal button cell will maintain data in the M48Z58/Y for an accumulated period of at least 10 years when  $V_{CC}$  is less than  $V_{SO}$ .

As system power returns and  $V_{CC}$  rises above  $V_{SO}$ , the battery is disconnected, and the power supply is switched to external  $V_{CC}$ . Normal RAM operation can resume  $t_{REC}$  after  $V_{CC}$  exceeds  $V_{PFD}$  (max).

For more information on Battery Storage Life refer to the Application Note AN1012.

### $V_{CC}$ Noise And Negative Going Transients

$I_{CC}$  transients, including those produced by output switching, can produce voltage fluctuations, resulting in spikes on the  $V_{CC}$  bus. These transients can be reduced if capacitors are used to store energy which stabilizes the  $V_{CC}$  bus. The energy stored in the bypass capacitors will be released as low going spikes are generated or energy will be absorbed when overshoots occur. A ceramic bypass capacitor value of  $0.1\mu\text{F}$  (see Figure 10) is recommended in order to provide the needed filtering.

In addition to transients that are caused by normal SRAM operation, power cycling can generate negative voltage spikes on  $V_{CC}$  that drive it to values below  $V_{SS}$  by as much as one volt. These negative spikes can cause data corruption in the SRAM while in battery backup mode. To protect from these voltage spikes, ST recommends connecting a schottky diode from  $V_{CC}$  to  $V_{SS}$  (cathode connected to  $V_{CC}$ , anode to  $V_{SS}$ ). (Schottky diode 1N5817 is recommended for through hole and MBRS120T3 is recommended for surface mount).

## MAXIMUM RATING

Stressing the device above the rating listed in the “Absolute Maximum Ratings” table may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the Operating sections of this specification is

not implied. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability. Refer also to the STMicroelectronics SURE Program and other relevant quality documents.
