

Typical unit

## FEATURES

- Industry-standard through-hole eighth-brick package with 0.9" x 2.3" x 0.36" outline dimensions
- Choice of two wide input ranges, 9 - 36 Vdc or 18-75 Vdc
- Fixed output from 3.3 to 24 Volts DC up to 75 Watts
- Synchronous rectification yields very high efficiency and low power dissipation
- Operating temperature range from -40 to +85°C. with derating
- Up to 1500 Volt DC isolation using Basic insulation
- Outstanding thermal performance and derating
- Extensive self-protection, overtemperature and overload features with no output reverse conduction
- On/Off control, trim and remote sense functions
- Designed to meet UL/EN/IEC 60950-1, CAN/CSA-C22.2 No. 60950-1 safety approvals and FCC RFI/EMI certification
- Pre-bias operation for startup protection

The UWE Series "Eighth-Brick" DC/DC Converters are high-current isolated power modules designed for use in high-density system boards.

## PRODUCT OVERVIEW

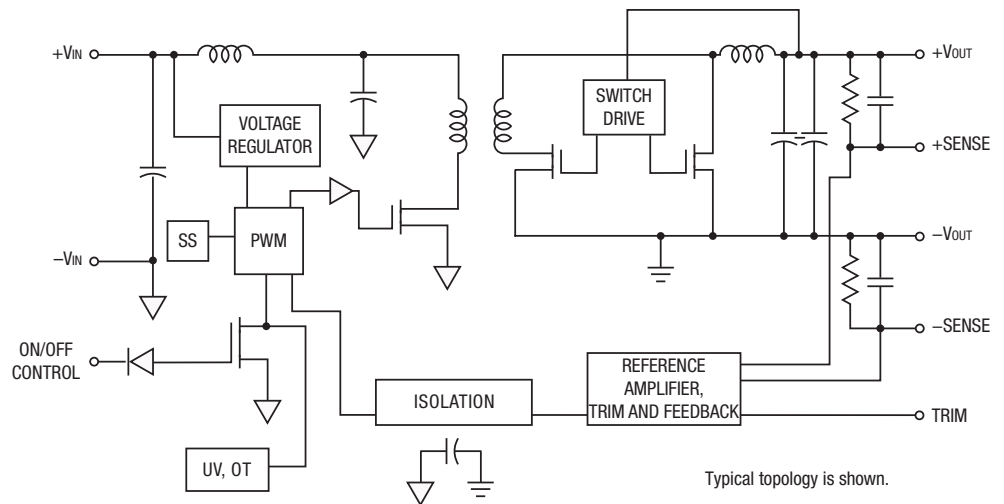

With dimensions of only 0.9 by 2.3 by 0.36 inches, the UWE series open frame DC/DC converters deliver up to 75 Watts in an industry-standard "eighth-brick" through-hole package. This format can plug directly into quarter-brick pinouts. Several standard fixed-output voltages from 3.3 Vdc to 24 Vdc assure compatibility in embedded equipment, CPU cards and instrument subsystems. The extended 4-to-1 input power range (9-36V) is ideal for battery-powered, telecom or portable applications. Very high efficiency means no fans or temperature deratings in many applications. An optional thermal mounting baseplate extends operation into most conceivable environments.

The synchronous rectifier design uses the maximum available duty cycle for greatest efficiency and low power dissipation with no reverse output conduction. Other features include low on-resistance FET's, planar magnetics and heavy-copper PC boards. These deliver low output noise, tight line/load regulation, stable no-load operation

and fast load step response. All units are precision assembled in a highly automated facility with ISO-traceable manufacturing quality standards.

Isolation of 1500 Volts assures safety and fully differential (floating) operation for greatest application flexibility. On-board Sense inputs compensate for line drop errors at high output currents. Outputs are trimmable within  $\pm 10\%$  of nominal voltage. The UWE series are functionally complete.

A wealth of protection features prevents damage to both the converter and outside circuits. Inputs are protected from undervoltage and outputs feature short circuit protection, overcurrent and excess temperature shut down. Overloads automatically recover using the "hiccup" technique upon fault removal. The UWE is designed to meet all standard safety and EMI/RFI certifications. All units meet RoHS-6 (no lead) hazardous materials certification.

Simplified Block Diagram

Typical topology is shown.

SPECIFICATION SUMMARY AND ORDERING GUIDE ①														
Root Model ①	Output						Input				Efficiency		Package (Case, Pinout)

### SPECIFICATION NOTES

- CAUTION: This product is not internally fused. To comply with safety agency certifications and to avoid injury to personnel or equipment, the user must supply an external fast-blow fuse to the input terminals. See fuse information.
- All models are tested and specified with external 1µF and 10µF paralleled ceramic/tantalum output capacitors and a 100 µF external input capacitor. All capacitors are low ESR types. These capacitors are necessary to accommodate our test equipment and may not be required to achieve specified performance in your applications. However, Murata Power Solutions recommends using these capacitors in your application. All models are stable and regulate within spec under no-load conditions. All specifications are typical unless noted. General conditions for Specifications are +25° C, Vin=nominal, Vout=nominal, full load. Adequate airflow must be supplied for extended testing under power.
  - Input Ripple Current is tested and specified over a 5 Hz to 20 MHz bandwidth. Input filtering is Cin=33 µF, Cbus=220 µF, Lbus=12 µH.
  - Note that Maximum Power Derating curves indicate an average current at nominal input voltage. At higher temperatures and/or lower airflow, the DC/DC converter will tolerate brief full current outputs if the total RMS current over time does not exceed the Derating curve. All Derating curves are presented at sea level altitude. Be aware that power dissipation degrades as altitude increases.
  - Mean Time Before Failure is calculated using the Telcordia (Belcore) SR-332 Issue 1, Case 3, Fits 266, ground fixed conditions, Tambient = +30° C, full output load, natural air convection.
  - The Remote On/Off Control is normally controlled by a switch or open collector or open drain transistor. But it may also be driven with external logic or by applying appropriate external voltages which are referenced to Input Common.
  - Short circuit shutdown begins when the output voltage degrades approximately 2% from the selected setting.
  - The outputs are not intended to sink appreciable reverse current.
  - Output noise may be further reduced by adding an external filter. See I/O Filtering and Noise Reduction. Larger caps (especially low-ESR ceramic capacitors) may slow transient response or degrade stability. Use only as much output filtering as needed to achieve your noise requirements and no more. Thoroughly test your system under full load with all components installed.
  - All models are fully operational and meet published specifications, including “cold start” at -40° C. At full power, the package temperature of all on-board components must not exceed +128° C.
  - Regulation specifications describe the deviation as the line input voltage or output load current is varied from a nominal midpoint value to either extreme.
  - If the user adjusts the output voltage, accuracy is dependent on user-supplied trim resistors. To achieve high accuracy, use ±1% or better tolerance metal-film resistors. If no trim is installed, the converter will achieve its rated accuracy. Do not exceed maximum power specifications when adjusting the output trim.
  - Output current limit and short circuit protection is non-latching. When the overcurrent fault is removed, the converter will immediately recover.
  - Alternate pin length and/or other output voltages may be available under special quantity order.
  - At zero output current, the output may contain low frequency components which exceed the ripple specification. The output may be operated indefinitely with no load.
  - Input Fusing: To ensure reverse input protection with full output load, always connect an external input fast-blow *fuse* in series with the +Vin input. Use approximately twice the full input current rating at the selected input voltage.
  - “Hiccup” overcurrent operation repeatedly attempts to restart the converter with a brief, full-current output. If the overcurrent condition still exists, the restart current will be removed and then tried again. This short current pulse prevents overheating and damaging the converter. Once the fault is removed, the converter immediately recovers normal operation.
  - Note that the converter will operate up to the rated baseplate maximum temperature with the baseplate installed and properly heat sunk. To avoid thermal self-protection shutdown, do not exceed this maximum baseplate temperature.
  - UWE-24/3-Q12 undervoltage shutdown of 8.0V is at half load.
  - UWE-24/3-Q12 output overvoltage protection requires 0.3A minimum load.
  - Pre-bias operation: Startup will succeed if the output setpoint voltage is higher than the pre-existing external output voltage.

**Soldering Guidelines**

Murata Power Solutions recommends the specifications below when installing these converters. These specifications vary depending on the solder type. Exceeding these specifications may cause damage to the product. Be cautious when there is high atmospheric humidity. We strongly recommend a mild pre-bake (100° C. for 30 minutes). Your production environment may differ; therefore please thoroughly review these guidelines with your process engineers.

Wave Solder Operations for through-hole mounted products (THMT)	
<b>For Sn/Ag/Cu based solders:</b>	
Maximum Preheat Temperature	115° C.
Maximum Pot Temperature	270° C.
Maximum Solder Dwell Time	7 seconds
<b>For Sn/Pb based solders:</b>	
Maximum Preheat Temperature	105° C.
Maximum Pot Temperature	250° C.
Maximum Solder Dwell Time	6 seconds

Absolute Maximum Ratings	
<b>Input Voltage</b>	
Continuous or transient, 100 mSec max.	50 Volts
<b>Output Power</b>	
	66-75 Watts, model dependent
<b>On/Off Control</b>	
	0V. min. to +Vin max.
<b>Input Reverse Polarity Protection</b>	
	See Fuse section.
<b>Output Current*</b>	
	Devices can withstand sustained short circuit without damage.
<b>Storage Temperature</b>	
	-40 to +125° C

Absolute maximums are stress ratings. Exposure of devices to any of these conditions may adversely affect long-term reliability. Proper operation under conditions other than those listed in the Performance/Functional Specifications Table is not implied or recommended.

\* The outputs are not intended to sink appreciable reverse current. If the outputs are forced to sink excessive current, damage may result.

**TECHNICAL NOTES**

**Input Fusing**

Certain applications and/or safety agencies may require the installation of fuses at the inputs of power conversion components. Fuses should also be used if the possibility of sustained, non-current-limited, input-voltage polarity reversals exist. For MPS UWE DC/DC Converters, you should use fast-blow type fuses, installed in the ungrounded input supply line. Refer to the specifications for fuse values.

All relevant national and international safety standards and regulations must be observed by the installer. For system safety agency approvals, the converters must be installed in compliance with the requirements of the end-use safety standard, e.g., IEC/EN/UL60950-1.

**Input Undervoltage Shutdown and Start-Up Threshold**

Under normal start-up conditions, devices will not begin to regulate until the ramping-up input voltage exceeds the Start-Up Threshold Voltage. Once operating, devices will not turn off until the input voltage drops below the Undervoltage Shutdown limit. Subsequent re-start will not occur until the input is brought back up to the Start-Up Threshold. This built in hysteresis prevents any unstable on/off situations from occurring at a single input voltage.

**Start-Up Time**

The  $V_{IN}$  to  $V_{OUT}$  Start-Up Time is the interval of time between the point at which the ramping input voltage crosses the Start-Up Threshold and the fully loaded output voltage enters and remains within its specified accuracy band. Actual measured times will vary with input source impedance, external input/output capacitance, and load. The UWE Series implements a soft start circuit that limits the duty cycle of its PWM controller at power up, thereby limiting the input inrush current.

The On/Off Control to  $V_{OUT}$  start-up time assumes the converter has its nominal input voltage applied but is turned off via the On/Off Control pin. The specification defines the interval between the point at which the converter is turned on and the fully loaded output voltage enters and remains within its specified accuracy band. Similar to the  $V_{IN}$  to  $V_{OUT}$  start-up, the On/Off Control to  $V_{OUT}$  start-up time is also governed by the internal soft start circuitry and external load capacitance.

The difference in start up time from  $V_{IN}$  to  $V_{OUT}$  and from On/Off Control to  $V_{OUT}$  is therefore insignificant.

**Input Source Impedance**

UWE converters must be driven from a low ac-impedance input source. The DC/DC's performance and stability can be compromised by the use of highly inductive source impedances. For optimum performance, components should be mounted close to the DC/DC converter. If the application has a high source impedance, low  $V_{IN}$  models can benefit from increased external input capacitance.

**I/O Filtering, Input Ripple Current, and Output Noise**

All models in the UWE Converters are tested/specified for input reflected ripple current and output noise using the specified external input/output components/circuits and layout as shown in the following two figures.

External input capacitors ( $C_{IN}$  in Figure 2) serve primarily as energy-storage elements, minimizing line voltage variations caused by transient IR drops in conductors from backplane to the DC/DC. Input caps should be selected for bulk capacitance (at appropriate frequencies), low ESR, and high rms-ripple-current ratings. The switching nature of DC/DC converters requires that dc voltage sources have low ac impedance as highly inductive source impedance can affect system stability. In Figure 2,  $C_{BUS}$  and  $L_{BUS}$  simulate a typical dc voltage bus. Your specific system configuration may necessitate additional considerations.

**Figure 2. Measuring Input Ripple Current**

In critical applications, output ripple/noise (also referred to as periodic and random deviations or PARD) may be reduced below specified limits using filtering techniques, the simplest of which is the installation of additional external output capacitors. These output caps function as true filter elements and should be selected for bulk capacitance, low ESR and appropriate frequency response. All external capacitors should have appropriate voltage ratings and be located as close to the converter as possible. Temperature variations for all relevant parameters should also be taken carefully into consideration.

The most effective combination of external I/O capacitors will be a function of line voltage and source impedance, as well as particular load and layout conditions. Our Applications Engineers can recommend potential solutions and discuss the possibility of our modifying a given device's internal filtering to meet your specific requirements. Contact our Applications Engineering Group for additional details.

In Figure 3, the two copper strips simulate real-world pcb impedances between the power supply and its load. In order to minimize measurement errors, scope measurements should be made using BNC connectors, or the probe ground should be less than 1/2 inch and soldered directly to the fixture.

**Figure 3. Measuring Output Ripple/Noise (PARD)**

**Floating Outputs**

Since these are isolated DC/DC converters, their outputs are "floating" with respect to their input. Designers will normally use the -Output as the ground/return of the load circuit. You can, however, use the +Output as ground/return to effectively reverse the output polarity.

**Minimum Output Loading Requirements**

UWE converters employ a synchronous-rectifier design topology and all models regulate within spec and are stable under no-load to full load conditions. Operation under no-load conditions however might slightly increase the output ripple and noise.

**Thermal Shutdown**

These UWE converters are equipped with thermal-shutdown circuitry. If environmental conditions cause the internal temperature of the DC/DC converter to rise above the designed operating temperature, a precision temperature sensor will power down the unit. When the internal temperature decreases below the threshold of the temperature sensor, the unit will self start. See Performance/Functional Specifications.

**Output Overvoltage Protection**

UWE output voltages are monitored for an overvoltage condition via magnetic feedback. The signal is coupled to the primary side and if the output voltage rises to a level which could be damaging to the load, the sensing circuitry will power down the PWM controller causing the output voltages to decrease. Following a time-out period the PWM will restart, causing the output voltages to ramp to their appropriate values. If the fault condition persists, and the output voltages again climb to excessive levels, the overvoltage circuitry will initiate another shutdown cycle. This on/off cycling is referred to as "hiccup" mode.

**Current Limiting**

As soon as the output current increases to substantially above its rated value, the DC/DC converter will go into a current-limiting mode. In this condition, the output voltage will decrease proportionately with increases in output current, thereby maintaining somewhat constant power dissipation. This is commonly referred to as power limiting. Current limit inception is defined as the point at which the full-power output voltage falls below the specified tolerance. See Performance/Functional Specifications. If the load current, being drawn from the converter, is significant enough, the unit will go into a short circuit condition as specified under "Performance."

**Short Circuit Condition**

When a converter is in current-limit mode, the output voltage will drop as the output current demand increases. If the output voltage drops too low, the magnetically coupled voltage used to develop primary side voltages will also drop, thereby shutting down the PWM controller. Following a time-out period, the PWM will restart causing the output voltages to begin ramping to their appropriate values. If the short-circuit condition persists, another shutdown cycle will be initiated. This on/off cycling is referred to as "hiccup" mode. The hiccup cycling reduces the average output current, thereby preventing internal temperatures from rising to excessive levels. The UWE is capable of enduring an indefinite short circuit output condition.

**Features and Options**

**On/Off Control**

The input-side, remote On/Off Control function can be ordered to operate with either polarity:

Positive-polarity models ("P" part-number suffix) are enabled when the On/Off Control is left open or is pulled high, as per Figure 4. Positive-polarity devices are disabled when the On/Off Control is pulled low.

Negative-polarity devices ("N" suffix) are off when the On/Off Control is open (or pulled high), and on when the On/Off Control is pulled low with respect to  $-V_{IN}$  as shown in Figure 5.

Figure 4. Driving the Positive Polarity On/Off Control Pin

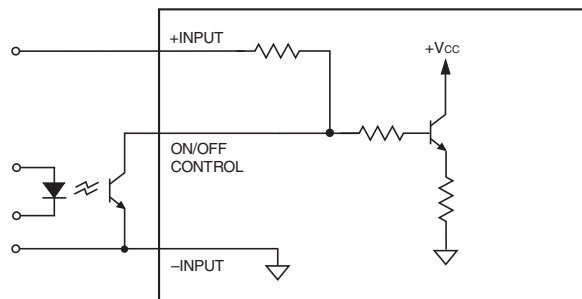

Figure 5. Driving the Negative Polarity On/Off Control Pin

Dynamic control of the remote on/off function is facilitated with a mechanical relay or an open-collector/open-drain drive circuit (optically isolated if appropriate). The drive circuit should be able to sink appropriate current (see Performance Specs) when activated and withstand appropriate voltage when deactivated. Applying an external voltage to the On/Off Control when no input power is applied to the converter can cause permanent damage to the converter.

**Trimming Output Voltage**

UWE converters have a trim capability that allows users to adjust the output voltages. Adjustments to the output voltages can be accomplished via a trim pot (Figure 6) or a single fixed resistor as shown in Figures 7 and 8. A single fixed resistor can increase or decrease the output voltage depending on its connection. The resistor should be located close to the converter and have a TCR less than 100ppm/°C to minimize sensitivity to changes in temperature. If the trim function is not used, leave the trim pin floating.

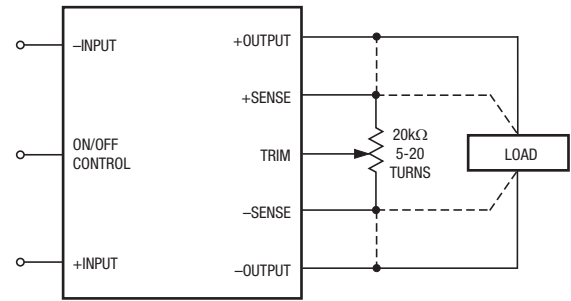

Figure 6. Trim Connections Using A Trimpot

Figure 7. Trim Connections To Increase Output Voltages Using a Fixed Resistor

Figure 8. Trim Connections To Decrease Output Voltages

A single resistor connected from the Trim to the +Output, or +Sense where applicable, will increase the output voltage in this configuration. A resistor connected from the Trim to the -Output, or -Sense where applicable, will decrease the output voltage in this configuration.

Trim adjustments greater than the specified range can have an adverse affect on the converter's performance and are not recommended. Excessive voltage differences between  $V_{OUT}$  and Sense, in conjunction with trim adjustment of the output voltage, can cause the overvoltage protection circuitry to activate (see Performance Specifications for overvoltage limits). Power derating is based on maximum output current and voltage at the converter's output pins. Use of trim and sense functions can cause output voltages to increase, thereby increasing output power beyond the converter's specified rating or cause output voltages to climb into the output overvoltage region. Therefore:

$$(V_{OUT \text{ at pins}}) \times (I_{OUT}) \leq \text{rated output power}$$

**Trim Equations**

Trim Up

Trim Down

3.3 Volt Output	
$R_{T\_UP} (k\Omega) = \frac{13.3(V_O - 1.226)}{V_O - 3.3} - 10.2$	$R_{T\_DOWN} (k\Omega) = \frac{16.31}{3.3 - V_O} - 10.2$
5 Volt Output	
$R_{T\_UP} (k\Omega) = \frac{20.4(V_O - 1.226)}{V_O - 5} - 10.2$	$R_{T\_DOWN} (k\Omega) = \frac{25.01}{5 - V_O} - 10.2$
12 Volt Output	
$R_{T\_UP} (k\Omega) = \frac{49.6(V_O - 1.226)}{V_O - 12} - 10.2$	$R_{T\_DOWN} (k\Omega) = \frac{60.45}{12 - V_O} - 10.2$
24 Volt Output	
$R_{T\_UP} (k\Omega) = \frac{101(V_O - 1.226)}{V_O - 24} - 10.2$	$R_{T\_DOWN} (k\Omega) = \frac{124.2}{24 - V_O} - 10.2$

**Note:** Resistor values are in kΩ. Adjustment accuracy is subject to resistor tolerances and factory-adjusted output accuracy.  $V_O$  = desired output voltage.

**Remote Sense Note:** The Sense and  $V_{OUT}$  lines are internally connected through low value resistors. Nevertheless, if the sense function is not used for remote regulation the user should connect the +Sense to + $V_{OUT}$  and -Sense to - $V_{OUT}$  at the DC/DC converter pins.

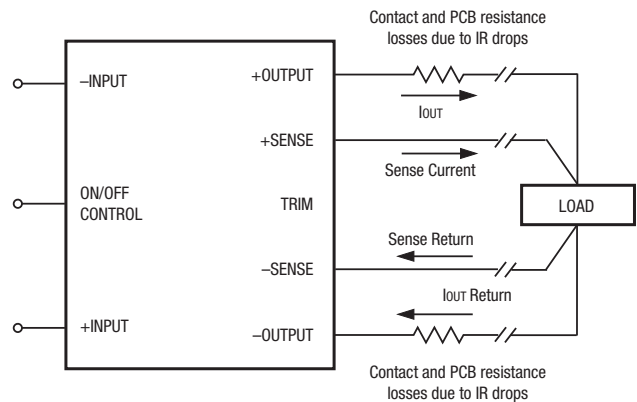

UWE series converters have a sense feature to provide point of use regulation, thereby overcoming moderate IR drops in pcb conductors or cabling. The remote sense lines carry very little current and therefore require minimal cross-sectional-area conductors. The sense lines are used by the feedback control-loop to regulate the output. As such, they are not low impedance points and must be treated with care in layouts and cabling. Sense lines on a pcb should be run adjacent to dc signals, preferably ground. In cables and discrete wiring applications, twisted pair or other techniques should be implemented.

UWE series converters will compensate for drops between the output voltage at the DC/DC and the sense voltage at the DC/DC provided that:

$$[V_{OUT(+)} - V_{OUT(-)}] - [Sense(+) - Sense(-)] \leq 5\% V_{OUT}$$

Output overvoltage protection is monitored at the output voltage pin, not the Sense pin. Therefore, excessive voltage differences between  $V_{OUT}$  and Sense in conjunction with trim adjustment of the output voltage can cause the overvoltage protection circuitry to activate (see Performance Specifications for overvoltage limits). Power derating is based on maximum output current and voltage at the converter's output pins. Use of trim and sense functions can cause output voltages to increase thereby increasing output power beyond the UWE's specified rating or cause output voltages to climb into the output overvoltage region. Also, the use of Trim Up and Sense combined may not exceed +10% of  $V_{OUT}$ . Therefore, the designer must ensure:

$$(V_{OUT \text{ at pins}}) \times (I_{OUT}) \leq \text{rated output power}$$

**PERFORMANCE DATA**

**UWE-24/3-Q12P**

Efficiency vs. Line Voltage and Load Current @ 25°C

Power Dissipation vs. Load Current @ 25°C

**UWE-24/3-Q12P**

Maximum Current Temperature Derating @ sea level  
(VIN = 12V, transverse airflow, no baseplate)

Maximum Current Temperature Derating @ sea level  
(VIN = 12V, transverse airflow, with baseplate)
