

## 5MHz, Single and Dual Precision Rail-to-Rail Input-Output (RRIO) Op Amps

The ISL28136 and ISL28236 are low-power single and dual operational amplifiers optimized for single supply operation from 2.4V to 5.5V, allowing operation from one lithium cell or two Ni-Cd batteries. These devices feature a gain-bandwidth product of 5MHz and are unity-gain stable with a -3dB bandwidth of 13MHz.

These devices feature an Input Range Enhancement Circuit (IREC) which enables them to maintain CMRR performance for input voltages greater than the positive supply. The input signal is capable of swinging 0.25V above the positive supply and to the negative supply with only a slight degradation of the CMRR performance. The output operation is rail-to-rail.

The parts typically draw less than 1mA supply current per amplifier while meeting excellent DC accuracy, AC performance, noise and output drive specifications. Operation is guaranteed over -40°C to +125°C temperature range.

### Ordering Information

PART NUMBER (Note)	PART MARKING	PACKAGE (Pb-Free)	PKG. DWG. #
ISL28136FHZ-T7*	GABP	6 Ld SOT-23 Tape and Reel	MDP0038
ISL28136FHZ-T7A*	GABP	6 Ld SOT-23 Tape and Reel	MDP0038
ISL28136FBZ	28136FBZ	8 Ld SOIC	MDP0027
ISL28136FBZ-T7*	28136FBZ	8 Ld SOIC Tape and Reel	MDP0027
Coming Soon ISL28236FBZ-T7*		8 Ld SOIC Tape and Reel	MDP0027
Coming Soon ISL28236FAZ-T7A*		8 Ld MSOP Tape and Reel	MDP0043

\* "-T7" and "-T7A" suffix is for tape and reel. Please refer to TB347 for details on reel specifications.

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

### Features

- 5MHz Gain bandwidth product @  $A_V = 100$
- 13MHz -3db unity gain bandwidth
- 900 $\mu$ A typical supply current (per amplifier)
- 150 $\mu$ V maximum offset voltage (8 Ld SO)
- 16nA typical input bias current
- Down to 2.4V single supply voltage range
- Rail-to-rail input and output
- Enable pin (ISL28136 only)
- -40°C to +125°C operation
- Pb-free plus anneal available (RoHS compliant)

### Applications

- Low-end audio
- 4mA to 20mA current loops
- Medical devices
- Sensor amplifiers
- ADC buffers
- DAC output amplifiers

### Pinouts

**Absolute Maximum Ratings** ( $T_A = +25^\circ\text{C}$ )

Supply Voltage	5.75V
Supply Turn On Voltage Slew Rate	1V/ $\mu\text{s}$

## Applications Information

### Introduction

The ISL28136 and ISL28236 are single and dual channel Bi-CMOS rail-to-rail input, output (RRIO) micropower precision operational amplifiers. The parts are designed to operate from single supply (2.4V to 5.5V) or dual supply ( $\pm 1.2V$  to  $\pm 2.75V$ ). The parts have an input common mode range that extends 0.25V above the positive rail and down to the negative supply rail. The output operation can swing within about 3mV of the supply rails with a 100k $\Omega$  load.

### Rail-to-Rail Input

Many rail-to-rail input stages use two differential input pairs, a long-tail PNP (or PFET) and an NPN (or NFET). Severe penalties have to be paid for this circuit topology. As the input signal moves from one supply rail to another, the operational amplifier switches from one input pair to the other causing drastic changes in input offset voltage and an undesired change in magnitude and polarity of input offset current.

The ISL28136 and ISL28236 achieve input rail-to-rail operation without sacrificing important precision specifications and degrading distortion performance. The devices' input offset voltage exhibits a smooth behavior throughout the entire common-mode input range. The input bias current versus the common-mode voltage range gives an undistorted behavior from typically down to the negative rail to 0.25V higher than the positive rail.

### Rail-to-Rail Output

A pair of complementary Bi-polar devices are used to achieve the rail-to-rail output swing. The PNP sinks current to swing the output in the negative direction. The NPN sources current to swing the output in the positive direction. The ISL28136 and ISL28236 with a 100k $\Omega$  load will swing to within 3mV of the positive supply rail and within 3mV of the negative supply rail.

### Results of Over-Driving the Output

Caution should be used when over-driving the output for long periods of time. Over-driving the output can occur in two ways. 1) The input voltage times the gain of the amplifier exceeds the supply voltage by a large value or, 2) The output current required is higher than the output stage can deliver. These conditions can result in a shift in the Input Offset Voltage ( $V_{OS}$ ) as much as 1 $\mu V/hr.$  of exposure under these conditions.

### IN+ and IN- Input Protection

All input terminals have internal ESD protection diodes to both positive and negative supply rails, limiting the input voltage to within one diode beyond the supply rails. They also contain back-to-back diodes across the input terminals ("Pin Descriptions" on page 10 - Circuit 1). For applications where the input differential voltage is expected to exceed 0.5V, an

external series resistor must be used to ensure the input currents never exceed 5mA (Figure 38).

FIGURE 38. INPUT CURRENT LIMITING

### Enable/Disable Feature

The ISL28136 offers an  $\overline{EN}$  pin that disables the device when pulled up to at least 2.0V. In the disabled state (output in a high impedance state), the part consumes typically 10 $\mu A$  at room temperature. The  $\overline{EN}$  pin has an internal pull down. If left open, the  $\overline{EN}$  pin will pull to the negative rail and the device will be enabled by default. The  $\overline{EN}$  pin should never be left floating. When not used, the  $\overline{EN}$  pin should either be left floating or connected to the V- pin.

By disabling the part, multiple ISL28136 parts can be connected together as a MUX. In this configuration, the outputs are tied together in parallel and a channel can be selected by the  $\overline{EN}$  pin. The loading effects of the feedback resistors of the disabled amplifier must be considered when multiple amplifier outputs are connected together. Note that feed through from the IN+ to IN- pins occurs on any Mux Amp disabled channel where the input differential voltage exceeds 0.5V (e.g., active channel  $V_{OUT} = 1V$ , while disabled channel  $V_{IN} = GND$ ), so the mux implementation is best suited for small signal applications. If large signals are required, use series IN+ resistors, or a large value  $R_F$ , to keep the feed through current low enough to minimize the impact on the active channel. See the "Limitations of the Differential Input Protection" section for more details.

### Limitations of the Differential Input Protection

If the input differential voltage is expected to exceed 0.5V, an external current limiting resistor must be used to ensure the input current never exceeds 5mA. For non-inverting unity gain applications, the current limiting can be via a series IN+ resistor, or via a feedback resistor of appropriate value. For other gain configurations, the series IN+ resistor is the best choice, unless the feedback ( $R_F$ ) and gain setting ( $R_G$ ) resistors are both sufficiently large to limit the input current to 5mA.

Large differential input voltages can arise from several sources:

- 1) During open loop (comparator) operation. Used this way, the IN+ and IN- voltages don't track, so differentials arise.
- 2) When the amplifier is disabled but an input signal is still present. An  $R_L$  or  $R_G$  to GND keeps the IN- at GND, while the varying IN+ signal creates a differential voltage. Mux Amp applications are similar, except that the active channel  $V_{OUT}$  determines the voltage on the IN- terminal.

3) When the slew rate of the input pulse is considerably faster than the op amp's slew rate. If the  $V_{OUT}$  can't keep up with the  $IN+$  signal, a differential voltage results, and visible distortion occurs on the input and output signals. To avoid this issue, keep the input slew rate below  $1.9V/\mu s$ , or use appropriate current limiting resistors.

Large (>2V) differential input voltages can also cause an increase in disabled  $I_{CC}$ .

**Using Only One Channel**

The ISL28236 is a dual op amp. If the application only requires one channel, the user must configure the unused channel to prevent it from oscillating. The unused channel will oscillate if the input and output pins are floating. This will result in higher than expected supply currents and possible noise injection into the channel being used. The proper way to prevent this oscillation is to short the output to the negative input and ground the positive input (as shown in Figure 39).

**FIGURE 39. PREVENTING OSCILLATIONS IN UNUSED CHANNELS**

**Current Limiting**

These devices have no internal current-limiting circuitry. If the output is shorted, it is possible to exceed the Absolute Maximum Rating for output current or power dissipation, potentially resulting in the destruction of the device.

**Power Dissipation**

It is possible to exceed the +125°C maximum junction temperatures under certain load and power-supply conditions. It is therefore important to calculate the maximum junction temperature ( $T_{JMAX}$ ) for all applications to determine if power supply voltages, load conditions, or package type need to be modified to remain in the safe operating area. These parameters are related as follows:

$$T_{JMAX} = T_{MAX} + (\theta_{JA} \times PD_{MAXTOTAL}) \tag{EQ. 1}$$

where:

- $PD_{MAXTOTAL}$  is the sum of the maximum power dissipation of each amplifier in the package ( $PD_{MAX}$ )
- $PD_{MAX}$  for each amplifier can be calculated as follows:

$$PD_{MAX} = 2 \times V_S \times I_{SMAX} + (V_S - V_{OUTMAX}) \times \frac{V_{OUTMAX}}{R_L} \tag{EQ. 2}$$

where:

- $T_{MAX}$  = Maximum ambient temperature
- $\theta_{JA}$  = Thermal resistance of the package
- $PD_{MAX}$  = Maximum power dissipation of 1 amplifier
- $V_S$  = Supply voltage (Magnitude of  $V_+$  and  $V_-$ )
- $I_{MAX}$  = Maximum supply current of 1 amplifier
- $V_{OUTMAX}$  = Maximum output voltage swing of the application
- $R_L$  = Load resistance
