1 INTRODUCTION

1.1 PURPOSE AND SCOPE

This document is a product specification, providing a description, specifications, and design related information on the IIM-42351, a 3-axis accelerometer device targeted at Industrial applications. The device is housed in a small 2.5x3x0.91 mm 14-pin LGA package.

1.2 PRODUCT OVERVIEW

The IIM-42351 is a 3-axis accelerometer in a small 2.5x3x0.91 mm (14-pin LGA) package. It also features a 2K-byte FIFO that can lower the traffic on the serial bus interface and reduce power consumption by allowing the system processor to burst read sensor data and then go into a low-power mode. IM-42351, with its 3-axis integration, enables manufacturers to eliminate the costly and complex selection, qualification, and system level integration of discrete devices, guaranteeing optimal motion performance for consumers.

The accelerometer supports four programmable full-scale range settings from $\pm 2g$ to $\pm 16g$. It includes multiple capabilities to enable tri-axial inclination measurements in Industrial applications:

- Low noise: 70 $\mu g/\sqrt{Hz}$
- Low power: 0.3 mA with all 3-axes delivering full performance

IIM-42351 also supports external clock input for highly accurate 31 kHz to 50k Hz clock, that helps to reduce system level sensitivity error, reduce ODR sensitivity to temperature and device to device variation.

Other industry-leading features include on-chip 16-bit ADCs, programmable digital filters, an embedded temperature sensor, and programmable interrupts. The device features I3CSM, I²C, and SPI serial interfaces, a VDD operating range of 1.71V to 3.6V, and a separate VDDIO operating range of 1.71V to 3.6V.

The host interface can be configured to support I3CSM slave, I²C slave, or SPI slave modes. The I3CSM interface supports speeds up to 12.5 MHz (data rates up to 12.5 Mbps in SDR mode, 25 Mbps in DDR mode), the I²C interface supports speeds up to 1 MHz, and the SPI interface supports speeds up to 24 MHz.

By leveraging its patented and volume-proven CMOS-MEMS fabrication platform, which integrates MEMS wafers with companion CMOS electronics through wafer-level bonding, InvenSense has driven the package size down to a footprint and thickness of 2.5 mm x 3 mm x 0.91 ;mm (14-pin LGA), to provide a very small yet high performance low cost package. The device provides high robustness by supporting 20,000g shock reliability.

4.4 SYSTEM BLOCK DIAGRAM

Note: The above block diagram is an example. Please refer to the pin-out (section 3.1) for other configuration options.

4.5 OVERVIEW

The IIM-42351 is comprised of the following key blocks and functions:

- Three-axis MEMS accelerometer sensor with 16-bit ADCs and signal conditioning
 - 20-bits data format support in FIFO for high-data resolution (see section 6 for details)
- I3CSM, I²C and SPI serial communications interfaces to Host
- Self-Test
- Clocking
- Sensor Data Registers
- FIFO
- Interrupts
- Digital-Output Temperature Sensor
- Bias and LDOs
- Charge Pump
- Standard Power Modes

4.6 THREE-AXIS MEMS ACCELEROMETER WITH 16-BIT ADCS AND SIGNAL CONDITIONING

The IIM-42351 includes a 3-Axis MEMS accelerometer. Acceleration along a particular axis induces displacement of a proof mass in the MEMS structure, and capacitive sensors detect the displacement. The IIM-42351 architecture reduces the accelerometers' susceptibility to fabrication variations as well as to thermal drift. When the device is placed on a flat surface, it will measure 0g on the X- and Y-axes and +1g on the Z-axis. The accelerometers' scale factor is calibrated at the factory and is nominally independent of supply voltage. The full-scale range of the digital output can be adjusted to ±2g, ±4g, ±8g and ±16g.

4.7 I3CSM, I²C AND SPI HOST INTERFACE

The IIM-42351 communicates to the application processor using an I3CSM, I²C, or SPI serial interface. The IIM-42351 always acts as a slave when communicating to the application processor.

4.8 SELF-TEST

Self-test allows for the testing of the mechanical and electrical portions of the sensors. The self-test for each measurement axis can be activated by means of the accelerometer self-test registers.

When the self-test is activated, the electronics cause the sensors to be actuated and produce an output signal. The output signal is used to observe the self-test response.

The self-test response is defined as follows:

$$\text{SELF-TEST RESPONSE} = \text{SENSOR OUTPUT WITH SELF-TEST ENABLED} - \text{SENSOR OUTPUT WITH SELF-TEST DISABLED}$$

When the value of the self-test response is within the specified min/max limits of the product specification, the part has passed self-test. When the self-test response exceeds the min/max values, the part is deemed to have failed self-test.

4.9 CLOCKING

The IIM-42351 has a flexible clocking scheme, allowing the internal clock source to be used for the internal synchronous circuitry. This synchronous circuitry includes the signal conditioning and ADCs, and various control circuits and registers.

The internal clock for IIM-42351 is generated by a relaxation oscillator. A highly accurate external clock may be used rather than the internal clock sources, if greater clock accuracy is desired. The CLKIN pin on IIM-42351 provides the ability to input an external clock. External clock input supports highly accurate clock input from 31 kHz to 50k Hz, resulting in improvement of the following:

- a) ODR uncertainty due to process, temperature, and design limitations. This uncertainty can be as high as $\pm 8\%$ in internal clock mode. The CLKIN, assuming a 50 ppm or better 32.768 kHz source, will improve the ODR accuracy from $\pm 80,000$ ppm to ± 50 ppm in RCOSC mode.
- b) Sophisticated systems can estimate ODR inaccuracy to some extent, but not to the extent improved by using CLKIN.
- c) System-level clock/sensor synchronization. When using CLKIN, the accelerometer is on the same clock as the host. There is no need to continually re-synchronize the sensor data as the sensor sample points and period are known to be in exact alignment with the common system clock.
- d) Other applications that benefit from CLKIN include navigation, robotics.

4.10 SENSOR DATA REGISTERS

The sensor data registers contain the latest accelerometer, and temperature measurement data. They are read-only registers and are accessed via the serial interface. Data from these registers may be read anytime.

4.11 INTERRUPTS

Interrupt functionality is configured via the Interrupt Configuration register. Items that are configurable include the interrupt pins configuration, the interrupt latching and clearing method, and triggers for the interrupt. Items that can trigger an interrupt are (1) new data is available to be read (from the FIFO and Data registers); (2) accelerometer event interrupts; (3) FIFO watermark; (4) FIFO overflow. The interrupt status can be read from the Interrupt Status register.

4.12 DIGITAL-OUTPUT TEMPERATURE SENSOR

An on-chip temperature sensor and ADC are used to measure the IIM-42351 die temperature. The readings from the ADC can be read from the FIFO or the Sensor Data registers.

Temperature data value from the sensor data registers can be converted to degrees centigrade by using the following formula:

$$\text{Temperature in Degrees Centigrade} = (\text{TEMP_DATA} / 132.48) + 25$$

FIFO_TEMP_DATA, temperature data stored in FIFO, can be 8-bit or 16-bit quantity. The 8-bit of temperature data stored in FIFO is limited to -40°C to 85°C range, while the 16-bit representation can support the full operating temperature range. It can be converted to degrees centigrade by using the following formula:

$$\text{Temperature in Degrees Centigrade} = (\text{FIFO_TEMP_DATA} / 2.07) + 25$$

4.13 BIAS AND LDOS

The bias and LDO section generate the internal supply and the reference voltages and currents required by the IIM-42351.

4.14 CHARGE PUMP

An on-chip charge pump generates the high voltage required for the MEMS oscillator.

4.15 STANDARD POWER MODES

The following table lists the user-accessible power modes for IIM-42351.

6 FIFO

The IIM-42351 contains a 2 kB FIFO register that is accessible via the serial interface. The FIFO configuration register determines which data is written into the FIFO. Possible choices include accelerometer data, temperature readings, and FSYNC input. A FIFO counter keeps track of how many bytes of valid data are contained in the FIFO.

6.1 PACKET STRUCTURE

The following figure shows the 8 and 16-byte FIFO packet structures supported in IIM-42351. Base data format for accelerometer is 16-bits per element. 20-bits data format support is included in one of the packet structures. When 20-bits data format is used, accelerometer data consists of 18-bits of actual data and the two lowest order bits are always set to 0. When 20-bits data format is used, the only FSR settings that are operational is $\pm 16g$ for accelerometer, even if the FSR selection register settings are configured for other FSR values. The accelerometer sensitivity scale factor value is and 8192 LSB/g.

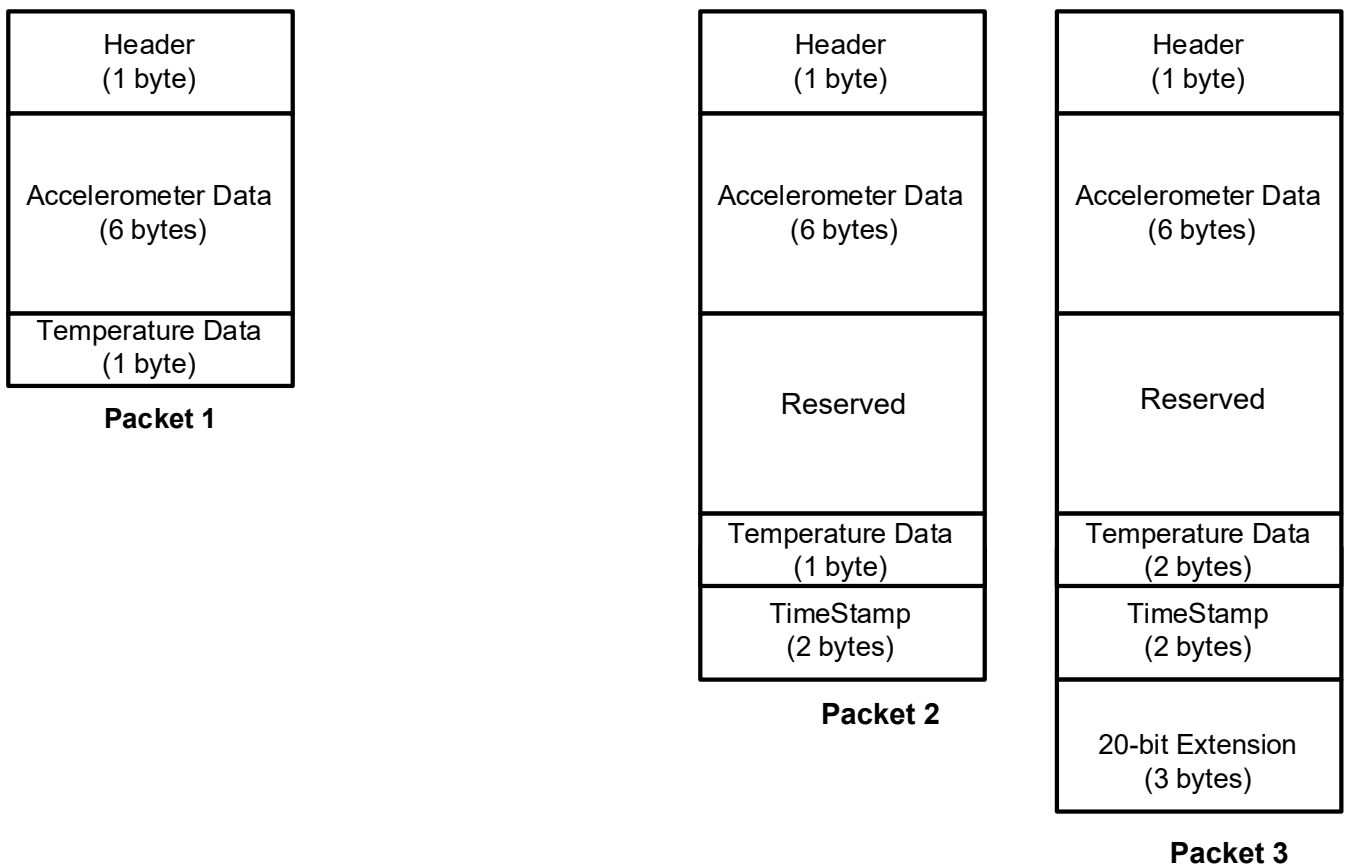

Figure 10. FIFO Packet Structure

Due to limitation on the number of bits, 8-bit Temperature data stored in FIFO is limited to -40°C to 85°C range. Either 16-bit Temperature data format (FIFO packet 3) or the value from the sensor data registers (TEMP_DATA) must be used to support a temperature measurements range of -40° to 105°C .

The rest of this sub-section describes how individual data is packaged in the different FIFO packet structures.

6.3 MAXIMUM FIFO STORAGE

The maximum number of packets that can be stored in FIFO is a variable quantity depending on the use case. As shown in Figure 11, the physical FIFO size is 2048 bytes. A number of bytes equal to the packet size selected (see section 5.1) is reserved to prevent reading a packet during write operation. Additionally, a read cache 2 packets wide is available.

When there is no serial interface operation, the read cache is not available for storing packets, being fed by the serial interface clock.

When serial interface operation happens, depending on the operation length and the packet size chosen, either 1 or 2 of the packet entries in read cache may become available for storing packets. In that case the total storage available is up to the maximum number of packets that can be accommodated in 2048 bytes + 1 packet size, depending on the packet size used.

Due to the non-deterministic nature of system operation, driver memory allocation should always be the largest size of 2080 bytes.

Figure 11. Maximum FIFO Storage

6.4 FIFO CONFIGURATION REGISTERS

The following control bits in bank 0, register 0x5Fh determine what data is placed into the FIFO. The values of these bits may change while the FIFO is being filled without corruption of the FIFO.

BIT	NAME	FUNCTION
4	FIFO_HIRES_EN	0: Default setting; Sensor data have regular resolution 1: Sensor data in FIFO will have extended resolution enabling the 20 Bytes packet
3	FIFO_TMST_FSYNC_EN	0: FIFO will only contain ODR timestamp information 1: FIFO can also contain FSYNC time and FSYNC tag for one ODR after an FSYNC event
1: 0	FIFO_PACKET_EN	00: Disable packet goes to FIFO 01: Enable Packet 1 goes to FIFO 10: Reserved 11: Enable Packet 2 goes to FIFO when FIFO_HIRES_EN=0 Enable Packet 3 goes to FIFO when FIFO_HIRES_EN=1

Configuration register settings above impact FIFO header and FIFO packet size as follows:

FIFO_HIRES_EN	FIFO_TMST_FSYNC_EN	FIFO_PACKET_EN	HEADER	PACKET SIZE
1	0	2'b_11	8'b_0111_10xx	20 Bytes
1	1	2'b_11	8'b_0111_11xx	20 Bytes
0	0	2'b_11	8'b_0110_10xx	16 Bytes
0	1	2'b_11	8'b_0110_11xx	16 Bytes
0	X	2'b_01	8'b_0100_00xx	8 Bytes
0	X	2'b_00	No FIFO writes	No FIFO writes

7 PROGRAMMABLE INTERRUPTS

The IIM-42351 has a programmable interrupt system that can generate an interrupt signal on the INT pins. Status flags indicate the source of an interrupt. Interrupt sources may be enabled and disabled individually. There are two interrupt outputs. Any interrupt may be mapped to either interrupt pin as explained in the register section. The following configuration options are available for the interrupts

- INT1 and INT2 can be push-pull or open drain
- Level or pulse mode
- Active high or active low

Additionally, IIM-42351 includes In-band Interrupt (IBI) support for the I3CSM interface.

8 APEX MOTION FUNCTIONS

The APEX (Advanced Pedometer and Event Detection – neXt gen) features of IIM-42631 consist of:

- Pedometer: Tracks Step count and issues a Step Detect Interrupt
- Tilt Detection: Issues an interrupt when the Tilt angle exceeds 35 degrees for more than a programmable time.
- Freefall Detection: Triggers an interrupt when device freefall is detected and outputs freefall duration.
- Tap Detection: Issues an interrupt when Tap is detected, along with a register containing the Tap Count.
- Wake on Motion (WoM): Detects motion when accelerometer samples exceed a programmable threshold. This motion event can be used to enable chip operation from sleep mode.
- Significant Motion Detector (SMD): Detects motion if WoM events are detected during a programmable time window (2s or 4s).

8.1 APEX ODR SUPPORT

APEX algorithms are designed to work with the accelerometer, for a variety of ODR settings. However, there is a minimum ODR required for each algorithm. The following table shows the relationship between the available accelerometer ODRs and the operation of the APEX algorithms. In order to allow more flexible operation where we can control the ODR of the APEX algorithms independent of the accelerometer ODR, we allow for an additional selection determined by the field DMP_ODR (DMP stands for Digital Motion Processor™, an architectural component of APEX). The tables below shows how DMP_ODR should be configured in relation to the accelerometer ODR and the expected performance.

ACCEL ODR	DMP_ODR	PEDOMETER	TILT DETECTION	FREEFALL DETECTION
< 25 Hz	X	Disabled	Disabled	Disabled
≥ 25 Hz	0 (25 Hz)	Low Power	Low Power	Low Power
≥ 50 Hz	2 (50 Hz)	Normal	Normal	Low Power
100 Hz	3 (100 Hz)	Normal (50Hz)	High Performance (50 Hz)	Normal
500Hz	1 (500Hz)	Disabled	High Performance (50 Hz)	High Performance

ACCEL ODR	TAP DETECTION
200 Hz	Low Power
500 Hz	Normal
1 kHz	High Performance
> 1 kHz	Disabled

If the accelerometer ODR is set below the minimum DMP ODR (25 Hz), the APEX features cannot be enabled.

When the accelerometer ODR needs to be set differently from the DMP ODR, only the integer multiple of DMP ODR for accelerometer sensor ODR is suitable to use with DMP. For example, when the accelerometer ODR is set as 200 Hz, the APEX features can be enabled with choices of 25 Hz, or 50 Hz, depending on the DMP_ODR register setting.

DMP ODR should not be changed on the fly. The following sequence should be followed for changing the DMP ODR:

1. Disable Pedometer, and Tilt Detection if they are enabled
2. Change DMP ODR
3. Set DMP_INIT_EN for one cycle (Register 0x4Bh in Bank 0)
4. Unset DMP_INIT_EN (Register 0x4Bh in Bank 0)
5. Enable APEX features of interest

8.2 DMP POWER SAVE MODE

DMP Power Save Mode can be enabled or disabled by DMP_POWER_SAVE (Register 0x56h in Bank 0). When the DMP Power Save Mode is enabled, APEX features are enabled only when WOM is detected. WOM must be explicitly enabled for the DMP to work in this mode. When WOM is not detected the APEX features are on pause. If the user does not want to use DMP Power Save Mode they may set DMP_POWER_SAVE = 0, and use APEX functions without WOM detection.

8.5 FREEFALL DETECTION PROGRAMMING

Freefall Detection detects device freefall. It uses a low-g and a high-g detector to detect freefall start and freefall end. It provides a trigger indicating freefall event and the freefall duration. The duration is given in number of samples and can be converted to freefall distance in meters by applying the following formula:

$$FF_DISTANCE = 0.5 * 9.81 * (FF_DUR * DMP_ODR_S)^2$$

Note: DMP_ODR_S is the duration of DMP_ODR expressed in seconds.

- Freefall Detection configuration parameters

9 DIGITAL INTERFACE

9.1 I3CSM, I²C AND SPI SERIAL INTERFACES

The internal registers and memory of the IIM-42351 can be accessed using I3CSM at 12.5 MHz (data rates up to 12.5 Mbps in SDR mode, 25 Mbps in DDR mode), I²C at 1 MHz or SPI at 24 MHz. SPI operates in 3-wire or 4-wire mode. Pin assignments for serial interfaces are described in Section 3.1.

9.2 I3CSM INTERFACE

I3CSM is a new 2-wire digital interface comprised of the signals serial data (SDA) and serial clock (SCLK). I3CSM is intended to improve upon the I²C interface, while preserving backward compatibility.

I3CSM carries the advantages of I²C in simplicity, low pin count, easy board design, and multi-drop (vs. point to point), but provides the higher data rates, simpler pads, and lower power of SPI. I3CSM adds higher throughput for a given frequency, in-band interrupts (from slave to master), dynamic addressing.

IIM-42351 supports the following features of I3CSM:

- SDR data rate up to 12.5Mbps
- DDR data rate up to 25Mbps
- Dynamic address allocation
- In-band Interrupt (IBI) support
- Support for asynchronous timing control mode 0
- Error detection (CRC and/or Parity)
- Common Command Code (CCC)

The IIM-42351 always operates as an I3CSM slave device when communicating to the system processor, which thus acts as the I3CSM master. I3CSM master controls an active pullup resistance on SDA, which it can enable and disable. The pullup resistance may be a board level resistor controlled by a pin, or it may be internal to the I3CSM master.

9.3 I²C INTERFACE

I²C is a two-wire interface comprised of the signals serial data (SDA) and serial clock (SCL). In general, the lines are open-drain and bi-directional. In a generalized I²C interface implementation, attached devices can be a master or a slave. The master device puts the slave address on the bus, and the slave device with the matching address acknowledges the master.

The IIM-42351 always operates as a slave device when communicating to the system processor, which thus acts as the master. SDA and SCL lines typically need pull-up resistors to VDDIO. The maximum bus speed is 1 MHz.

The slave address of the IIM-42351 is b110100X, which is 7 bits long. The LSB bit of the 7-bit address is determined by the logic level on pin AP_AD0. This allows two IIM-42351s to be connected to the same I²C bus. When used in this configuration, the address of one of the devices should be b1101000 (pin AP_AD0 is logic low) and the address of the other should be b1101001 (pin AP_AD0 is logic high).

9.4 I²C COMMUNICATIONS PROTOCOL

START (S) and STOP (P) Conditions

Communication on the I²C bus starts when the master puts the START condition (S) on the bus, which is defined as a HIGH-to-LOW transition of the SDA line while SCL line is HIGH (see figure below). The bus is considered to be busy until the master puts a STOP condition (P) on the bus, which is defined as a LOW to HIGH transition on the SDA line while SCL is HIGH (see figure below).

Additionally, the bus remains busy if a repeated START (Sr) is generated instead of a STOP condition.

Figure 12. START and STOP Conditions

Data Format / Acknowledge

I²C data bytes are defined to be 8-bits long. There is no restriction to the number of bytes transmitted per data transfer. Each byte transferred must be followed by an acknowledge (ACK) signal. The clock for the acknowledge signal is generated by the master, while the receiver generates the actual acknowledge signal by pulling down SDA and holding it low during the HIGH portion of the acknowledge clock pulse.

Communications

After beginning communications with the START condition (S), the master sends a 7-bit slave address followed by an 8th bit, the read/write bit. The read/write bit indicates whether the master is receiving data from or is writing to the slave device. Then, the master releases the SDA line and waits for the acknowledge signal (ACK) from the slave device. Each byte transferred must be followed by an acknowledge bit. To acknowledge, the slave device pulls the SDA line LOW and keeps it LOW for the high period of the SCL line. Data transmission is always terminated by the master with a STOP condition (P), thus freeing the communications line. However, the master can generate a repeated START condition (Sr), and address another slave without first generating a STOP condition (P). A LOW to HIGH transition on the SDA line while SCL is HIGH defines the stop condition. All SDA changes should take place when SCL is low, with the exception of start and stop conditions.

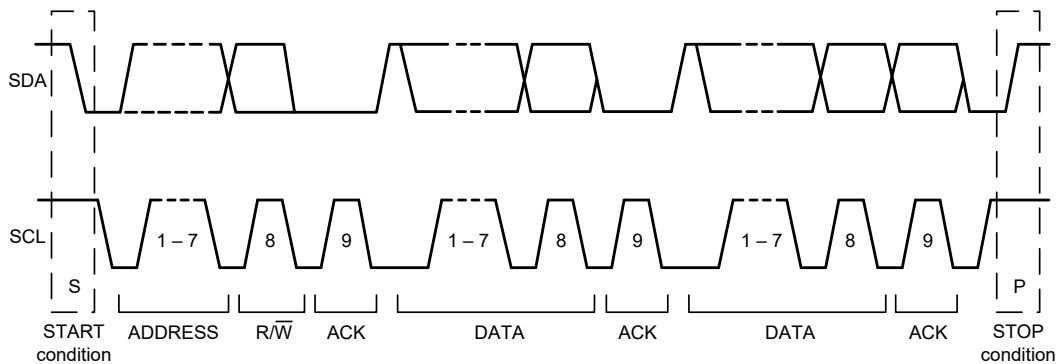

Figure 13. Complete I²C Data Transfer

To write the internal IIM-42351 registers, the master transmits the start condition (S), followed by the I²C address and the write bit (0). At the 9th clock cycle (when the clock is high), the IIM-42351 acknowledges the transfer. Then the master puts the register address (RA) on the bus. After the IIM-42351 acknowledges the reception of the register address, the master puts the register data onto the bus. This is followed by the ACK signal, and data transfer may be concluded by the stop condition (P). To write multiple bytes after the last ACK signal, the master can continue outputting data rather than transmitting a stop signal. In this case, the IIM-42351 automatically increments the register address and loads the data to the appropriate register. The following figures show single and two-byte write sequences.

Single-Byte Write Sequence

Master	S	AD+W		RA		DATA		P
Slave			ACK		ACK		ACK	

Burst Write Sequence

Master	S	AD+W		RA		DATA		DATA		P
Slave			ACK		ACK		ACK		ACK	

To read the internal IIM-42351 registers, the master sends a start condition, followed by the I²C address and a write bit, and then the register address that is going to be read. Upon receiving the ACK signal from the IIM-42351, the master transmits a start signal followed by the slave address and read bit. As a result, the IIM-42351 sends an ACK signal and the data. The communication ends with a not acknowledge (NACK) signal and a stop bit from master. The NACK condition is defined such that the SDA line remains high at the 9th clock cycle. The following figures show single and two-byte read sequences.

Single-Byte Read Sequence

Master	S	AD+W		RA		S	AD+R			NACK	P
Slave			ACK		ACK			ACK	DATA		

Burst Read Sequence

Master	S	AD+W		RA		S	AD+R			ACK		NACK	P
Slave			ACK		ACK			ACK	DATA		DATA

9.6 SPI INTERFACE

The IIM-42351 supports 3-wire or 4-wire SPI for the host interface. The IIM-42351 always operates as a Slave device during standard Master-Slave SPI operation.

With respect to the Master, the Serial Clock output (SCLK), the Serial Data Output (SDO), the Serial Data Input (SDI), and the Serial Data IO (SDIO) are shared among the Slave devices. Each SPI slave device requires its own Chip Select (CS) line from the master.

CS goes low (active) at the start of transmission and goes back high (inactive) at the end. Only one CS line is active at a time, ensuring that only one slave is selected at any given time. The CS lines of the non-selected slave devices are held high, causing their SDO lines to remain in a high-impedance (high-z) state so that they do not interfere with any active devices.

SPI Operational Features

1. Data is delivered MSB first and LSB last
2. Data is latched on the rising edge of SCLK
3. Data should be transitioned on the falling edge of SCLK
4. The maximum frequency of SCLK is 24 MHz
5. SPI read operations are completed in 16 or more clock cycles (two or more bytes). The first byte contains the SPI Address, and the following byte(s) contain(s) the SPI data. The first bit of the first byte contains the Read/Write bit and indicates the Read (1) operation. The following 7 bits contain the Register Address. In cases of multiple-byte Reads, data is two or more bytes:

SPI Address format

MSB							LSB
R/W	A6	A5	A4	A3	A2	A1	A0

SPI Data format

MSB							LSB
D7	D6	D5	D4	D3	D2	D1	D0

6. SPI write operations are completed in 16 clock cycles (two bytes). The first byte contains the SPI Address, and the second byte contains the SPI data. The first bit of the first byte contains the Read/Write bit and indicates the Write (0) operation. The following 7 bits contain the Register Address.
7. Supports Single or Burst Reads and Single Writes.

12 USE NOTES

12.1 ACCELEROMETER MODE TRANSITIONS

When transitioning from accelerometer Low Power (LP) mode to accelerometer Low Noise (LN) mode, if ODR is 6.25 Hz or lower, software should change ODR to a value of 12.5 Hz or higher, because accelerometer LN mode does not support ODR values below 12.5 Hz.

When transitioning from accelerometer LN mode to accelerometer LP mode, if ODR is greater than 500 Hz, software should change ODR to a value of 500 Hz or lower, because accelerometer LP mode does not support ODR values above 500 Hz.

12.2 ACCELEROMETER LOW POWER (LP) MODE AVERAGING FILTER SETTING

Software drivers provided with the device use Averaging Filter setting of 16x. This setting is recommended for meeting Android noise requirements in LP mode, and to minimize accelerometer offset variation when transitioning from LP to Low Noise (LN) mode. 1x averaging filter can be used by following the setting configuration shown in section 14.38.

12.3 SETTINGS FOR I²C, I3CSM, AND SPI OPERATION

Upon bootup the device comes up in SPI mode. The following settings should be used for I²C, I3CSM, and SPI operation.

Scenario 1: INT1/INT2 pins are used for interrupt assertion in I3CSM mode.

REGISTER FIELD	I ² C DRIVER SETTING	I3C SM DRIVER SETTING	SPI DRIVER SETTING

I3C_BUS_MODE (bit 6, register INTF_CONFIG4, address 0x7A, bank 1)	0	0	0
I2C_SLEW_RATE (bits 5:3, register DRIVE_CONFIG, address 0x13, bank 0)	1	0	0
SPI_SLEW_RATE (bits 2:0, register DRIVE_CONFIG, address 0x13, bank 0)	1	5	5

12.4 ANTI-ALIAS FILTER OPERATION

Use of Anti-Alias Filter is supported only for Low Noise (LN) mode operation. The host is responsible for keeping the UI path in LN mode while Anti-Alias Filter are turned on.

12.5 EXTERNAL CLOCK INPUT EFFECT ON ODR

ODR values supported by the device scale with external clock frequency, if external clock input is used. The ODR values shown in the datasheet are supported with external clock input frequency of 32 kHz. For any other external clock input frequency, these ODR values will scale by a factor of (External clock value in kHz/32). For example, if an external clock frequency of 32.768 kHz is used, instead of ODR value of 500 Hz, it will be $500 * (32.768/32) = 512$ Hz.

12.6 INT_ASYNC_RESET CONFIGURATION

For register INT_CONFIG1 (bank 0 register 0x64) bit 4 INT_ASYNC_RESET, user should change setting to 0 from default setting of 1, for proper INT1 and INT2 pin operation.

12.7 FIFO TIMESTAMP INTERVAL SCALING

When RTC_MODE =1 (bank 0 register 0x4D bit2) and register INTF_CONFIG5 (bank 1 register 0x7B) bit 2:1 (PIN9_FUNCTION) is set to 10 for CLKIN input;

THEN

Timestamp interval reported in FIFO requires scaling by a factor of 32.768/30. For example, when ODR = 1 kHz, the true timestamp interval should be 1000 μ s. But the value in FIFO toggles between 915 and 916 μ s. After scaling $915.5 * 32.768/30 = 1000$ μ s.

ELSE

Timestamp interval reported in FIFO requires scaling by a factor of 32/30. For example when ODR = 1 kHz, the true timestamp interval should be 1000 μ s. But the value in FIFO toggles between 937 and 938 μ s. After scaling $937.5 * 32/30 = 1000$ μ s.

Detailed register descriptions are provided in the sections that follow. Please note the following regarding Clock Domain for each register:

- Clock Domain: SCLK_UI means that the register is controlled from the UI interface

Register fields marked as Reserved must not be modified by the user. The Reset Value of the register can be used to determine the default value of reserved register fields, and unless otherwise noted this default value must be maintained even if the values of other register fields are modified by the user.

13.6 REGISTER VALUES MODIFICATION

The only register settings that user can modify during sensor operation are for ODR selection, FSR selection, and sensor mode changes (register parameters ACCEL_ODR, ACCEL_FS_SEL, ACCEL_MODE). User must not modify any other register values during sensor operation. The following procedure must be used for other register values modification.

- Turn Accel Off
- Modify register values
- Turn Accel On

Invalid Data Generation: FIFO/Sense Registers may contain invalid data under the following conditions:

- a) From power on reset to first ODR sample of any sensor (accel, temp sensor)
- b) When any sensor is disabled (accel, temp sensor)
- c) When accel is enabled with different ODRs. In this case, the sensor with lower ODR will generate invalid samples when it has no new data.

Invalid data can take special values or can hold last valid sample received. For -32768 to be used as a flag for invalid accel samples, the valid accel sample range is limited in such case as well. Bit 7 of INTF_CONFIG0 controls what values invalid (and valid) samples can take as shown above.
